(1) Allied substances are ground up together and macerated in water with some crystals of thymol (e.g., all the common flat fish or all the common shell-fish). This is then filtered, the filtrate evaporated to dryness at 56° C. over a water-bath or in a vacuum, and the resulting powder ground up. This, used with decinormal soda, makes a good group test powder, consisting of proteins, salts, and other substances.

(2) Many proteins, of course, cannot be prepared in this way; not a powder, but a gummy syrup remains, which refuses to be desiccated by any process, or takes on the form of hard toffee. In this case one is compelled to redissolve in water while wet, and precipitate by alcohol or acetone, filter, and dry the precipitate in alcohol or ether. It must be ascertained that the fluid used is an equally good precipitant for each substance.

(3) A third method is to prepare the proteins separately in powder form, and then to mix them in equal quantities and dissolve or suspend in water or centinormal soda with carbolic acid ¼ per cent. Such a "solution" is effective, and will remain "active" for at least three or four years, as will be shown later on. This is a most convenient way of performing the tests, and it is the one I am using at the present time, saturated solutions being employed.

(4) A simpler method is of use in some cases—viz., boiling several foodstuffs together and testing with the filtrate, but this I am investigating further.

As an example, beef, mutton, pork, and egg were pounded up together and extracted with water; this was boiled and then filtered. The filtrate was then concentrated by evaporation. This was used as a test solution on an egg-sensitive subject (C. L. P.) and an enormous dermal reaction resulted.

The illustration shows that the group test is effective. Other cases have given the same result. From several experiments made it is evident that eight different proteins may be mixed together for a single group test. If a positive reaction is obtained from the group solution, then each individual member of the group must be tested out.

Activity of the Test Substance.

It is essential to know that the test substance is active. Various names have been given to this property of giving a dermal reaction, or of giving a somatic reaction—e.g., urticaria, diarrhœa, asthma, &c. By analogy with anaphylactic phenomena this property has been called anaphylactogenic; this, however, presumes an unproven theory. I shall therefore merely call it active in the sense in which I am speaking—i.e., capable of giving a dermal reaction, or of producing the characteristic reaction in the individual possessing the idiosyncrasy to it.

The only method I know of testing this activity is to make a test on an individual with a known idiosyncrasy. The value of this is, of course, greatly limited. I therefore asked Dr. S. R. Gloyne to inject guinea-pigs with different substances—various fish proteins, egg albumin, oat protein, &c.—to see if we could produce a sensitiveness to these substances and so have a method of testing their activity. No such sensitive state, however, could be produced.

Since this was written, Dr. J. Freeman, of St. Mary's, has demonstrated a remarkable experiment upon himself. Intradermal injections of serum from a hay-fever patient followed by intravenous injection of the appropriate pollen resulted in a huge urticarial reaction. Dr. Gloyne repeated this experiment for me on the guinea-pig and rabbit, but it gave a negative result. Serum from an asthmatic extremely sensitive to horse-hair was injected intradermally into a rabbit; within half an hour horse-hair protein was injected intravenously; no reaction occurred. The serum and the horse-hair protein were then injected simultaneously intradermally into a guinea-pig; again there was no reaction. We have, therefore, to rely on patients with a known idiosyncrasy. From many tests the following facts have emerged.

The powdered proteins if kept dry appear to remain active indefinitely. Powdered proteins suspended in ¼ per cent. carbolic acid in water or normal saline will remain active for at least three or four years.

1. In the spring of 1921 a little girl, K. W., who was extremely sensitive to egg, was tested with a 1 in 100 solution of egg-white with ¼ per cent. carbolic acid. A marked reaction was obtained. In March, 1925, this same solution was used on another egg-sensitive individual (C. L. P.); a very marked reaction was obtained. This had remained active for four years.

2. A solution of oat protein produced a marked reaction on W. A. in 1921; in 1923 another test was made with this same solution and a very marked reaction resulted.

Effect of Heat.—As shown above, with egg-white, boiling does not appear to destroy the activity of some of the test substances. As another example: The filtrate from macerated herring can be boiled and filtered, and the filtrate boiled again and filtered and still remain powerfully active, and thus one can obtain a perfectly clear fluid for testing or injection. R. P. Wodehouse[1] writes that J. L. Goodale showed that "as a general rule vegetable foods, boiled or moderately cooked in any way, furnished just as powerful anaphylactogens as the corresponding raw foods, thus eliminating, in these, all heat coagulable proteins as possible anaphylactogenic factors. In the case of the fruits, however, this is not so, for the weight of evidence seems to show that heating destroys their anaphylactogenic properties." This last statement I have not been able to test.

Significance of the Reaction.

A well-marked dermal reaction, if the controls are negative, usually denotes a sensitiveness to the substance employed, but it does not invariably follow that the subject has any pathological reaction to it in the ordinary course of life. One patient, for example, gives a well-marked reaction to rice protein, and has severe asthma. He can, however, eat rice without any apparent discomfort, and withholding rice produced no amelioration of his asthma, and no immunity from his attacks was given by subcutaneous injections of rice protein. In other cases, however, there is, without a doubt, a close and direct ætiological relationship. For example:—

While testing K. W., a little girl who is egg-sensitive, with egg albumin, the dermal reaction was intense, and the small amount of egg albumin absorbed produced asthma and vomiting and bloodshot eyes.

W. A. was extremely sensitive to oat protein, less so to middlings. I commenced by giving injections of middlings protein. One day a change was made to oat protein. In error my clinical assistant gave a larger dose than was intended and 4 minims of a 1 in 400 solution were given; the man was free from asthma at the time. In a few moments his eyes began to run profusely, then paroxysms of sneezing seized him, and in a few minutes his chest was in the throes of an asthmatic attack. Neurosis could not have played a part, for the patient was unaware of any change in the injection.

C. L. P., an egg-sensitive man, has very kindly allowed me to make a great number of experimental tests on his arm. Although large dermal reactions had been obtained many times no general reaction occurred. One day, however, I was testing with proteins obtained from birds' egg other than the hen and reptilian eggs. A very intense reaction was set up by duck's egg and I failed to wipe off the protein sufficiently soon. Nausea and asthma occurred.

W. B., a severe asthmatic, was extremely sensitive to horse-hair and to the pollens of *Holcus lanatus* (Yorkshire fog grass) and rye grass. He begged for heroic treatment. A comparatively big dose of horse-hair protein was therefore injected; within half an hour he had severe asthma, and within an hour he had urticarial lumps all over the body and in the angle of the left eye.

---

[1] Boston Med. and Surg. Jour., August, 1916, Preparation of Vegetable Food Proteins for Anaphylactic Tests.

Application of a Discovered Idiosyncrasy.

This is not so simple as might appear from the literature. I have made hundreds of tests on scores of patients and cannot yet be enthusiastic about the practical outcome of it all, although I am convinced that the subject is worth pursuing. I have attempted to desensitise several patients, and though some of them have declared themselves improved, I have not succeeded in abolishing the dermal reaction. I have given injections of the following proteins: oats, fish, rice, cat's hair, horse-hair, and egg.

W. B. had a four months' course of injections of horse-hair protein and the pollen of *Holcus lanatus* and rye grass; at the end of four months his dermal reactions were still very marked (by this I mean a wheal the size of a florin and a red zone 8 cm. × 5 cm.), though he expressed himself as "a thousand times better."

These experiences are not in accord with those published by some other writers, who say that the dermal reaction progressively lessens with the progress of the treatment. Again, many patients with a known idiosyncrasy are absolutely compelled to avoid, and do avoid, the offending substance, and yet they have asthma. It is true there may be other things to which they are sensitive, but one is forced to the conclusion that we are far from the solution of the riddle, and one cannot fail to view very critically many of the glowing therapeutic results that have been published, and to wonder what the subsequent history of these patients will show. Asthma patients are extraordinarily susceptible to suggestion, and it is very hard to eliminate this factor, although I have tried to do so as far as possible in my cases. Some patients have been greatly benefited by the dermal tests which they imagined to be injections.

In any large series of cases treatment, on old traditional lines, with a mixture of potassium iodide, arsenic, lobelia, and stramonium, will yield a considerable percentage of satisfactory results, as also will treatment by vaccines. Moreover, asthma is so suspiciously like a neurosis in many ways that one has to be exceedingly careful before publishing results, and employing the famous *post hoc ergo propter hoc* argument that has done more than anything else perhaps to hinder the progress of medical science. There is no doubt that all the elaborate ritual of the skin tests greatly impresses the patient, and some of the substances used are so ludicrous that orthodox medicine appears to be left far behind and fascinating and mysterious vistas to be opening. The therapeutic effect of this cannot be ignored.

There is much work to be done. Every general practitioner can help. If he will keep his eyes open for cases of idiosyncrasy of all kinds he will find them. If he has a clue it is easy to make preliminary investigation with the crude article as mentioned above. Having obtained a reaction, it is then worth while having the pure protein made up by a good firm of chemists who are interested in this work, in different dilutions in carbol saline, say 1 in 100, 1 in 1000, 1 in 10,000, 1 in 50,000, and 1 in 100,000, and see which dilution fails to give a reaction. This having been determined, a strength intermediate between this and the next dilution should be used for injections, beginning with 0·1 c.cm. and working up to 1 c.cm., the rapidity depending on the reaction. After this the next strength is taken and so on. The results, whether positive or negative, should be published. Thus there will become available further materials for the study of idiosyncrasy and desensitisation.

Efficacy of Certain Commercial Proteins.

Whenever possible I have tested certain commercial test proteins on patients with a proved idiosyncrasy. Some I have found efficient, others inert. I am inclined to think that one firm loses a good deal of the protein in the filtering process employed. The preparations in fluid form are much more convenient to use than those in a boro-glyceride base. For group tests the solutions must be of sufficient strength.

So far as I know, only one firm employs the method of precipitating the pure protein by alcohol or acetone and immediately redissolving this, determining the strength of the solution obtained by an estimation of the nitrogen content. These test solutions, when put up as single tests, I have found active and productive of marked reactions. The multiple tests, however, I have not found uniformly satisfactory, probably because the concentration is not sufficiently strong in all cases.

Conclusions.

1. Group testing is efficient if the solutions employed are not too weak. 2. Proteins, it appears, will keep active in solution with ¼ per cent. or ½ per cent. carbolic for at least two years, and this is a convenient method of keeping test group solutions. 3. The best method of preparing proteins depends upon the use to be made of them. As a general rule it may be said that the powder form is the most satisfactory. Often, however, the powders become very insoluble, in which case precipitation and immediate re-solution is the best method. 4. It appears that many of the substances used can be boiled without altering their activity. 5. The existence of a dermal reaction, even a well-marked one, must not be taken as proof positive of an ætiological relationship between the substance producing this reaction and the symptoms of the patient, though it must not be ignored without consideration. 6. It is too early to dogmatise about the therapeutic application of the discovery of an idiosyncrasy. 7. To sit down to a case of some obscure malady with a miscellany of test proteins is not likely to yield any very useful result, but to investigate any case of strongly suspected idiosyncrasy, particularly from the point of view of desensitisation, and to publish it, will yield valuable material for the study of idiosyncrasy and its treatment.

I would express my great indebtedness to Dr. S. R. Gloyne, pathologist to the City of London Hospital for Diseases of the Heart and Lungs, for invaluable help; to Mr. Smart, Chief Laboratory Assistant, and to Mr. Laval Charles Proudfoot, who has most kindly, from motives of pure scientific interest, allowed me to perform a large number of experimental tests upon him.

CANCER OF THE BREAST.

AN ATTEMPT TO ESTIMATE THE DURATION OF LIFE AFTER OPERATION.

By S. WYARD, M.D., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE CANCER HOSPITAL (FREE), S.W.

At the request of the Medical Committee of the Cancer Hospital I have endeavoured to trace all the patients operated on in the hospital during the years 1905–1914 inclusive; to determine the length of life after the operation; and, when the patient has deceased, the cause of death. In pursuit of this information 560 inquiries were sent out and 279 answers were received. Unfortunately, 11 of the answers contained only the bare statement that the patient is dead and I have failed to discover anything further concerning these. In 50 per cent., therefore, the case was traced directly. By the kindness and assistance of the Registrar-General search was then made through the registers of deaths for the remaining 281, with the result that the date and cause of death were ascertained in another 197, but the names of 84 could not be found in the registers. Of the latter nothing can be discovered. Some (possibly, or even probably, a considerable proportion) are still alive. The failure to trace any particular person may be due to the fact that she is still alive; that she has changed her name, either by marriage or otherwise; that she has left the country and resides or has died abroad; that, being still alive, she has changed her address and left at her old residence no information by which it is possible to find her. Thus, of the 560 cases operated on in ten years the fate of 476 (85 per cent.) is known, though for 11 of these neither the date nor cause of death can be stated. So, then, 431 (77 per cent.) are known to be dead, 45 (8 per cent.) were alive at the time of inquiry (June, 1924)—i.e., they were alive ten years or more after the operation. Of those deceased 36 (6 per cent.) had survived ten or more years after operation, making a total of 81 (14 per cent.). Eighty-four cases remain, of whom nothing is known subsequent to their discharge from hospital.

How this lacuna in my information affects the final analysis is, of course, quite impossible to determine. It is possible that some are still alive. In any case the figures above, so far as they deal with survivals and the number who lived ten years or more after operation, are minimal, and were all the cases traced, could not suffer any diminution, but might, just possibly, be increased. These figures are perhaps more easily appreciated from Table I.

TABLE I.

Total number of patients.	Traced.							Total untraced.
	Total.	Living at date of inquiry.	Lived 10 or more years after operation.	Dead at time of inquiry.				
				Died of cancer.	Died of dis. other than cancer.	Cause of death unknown.	Total.	
560	476 (85 %)	45 (8 %)	81 (14 %)	379 (68 %)	41 (7 %)	11 (2 %)	431 (77 %)	84 (15 %)

Certified Causes of Death and Date After Operation.

Death was certified due to causes other than cancer in 47 cases, but in 6 of these—viz., phthisis 2, pleurisy and bronchitis 3, and pleurisy with effusion 1—there is a strong suspicion that the fatal lesion was in reality a secondary growth. It seems certain, however, that 41 (7 per cent.) of the deaths were not due to recurrence or metastasis. The causes certified were as shown in Table II.

TABLE II.

A. = Age at death. B. = Months after operation.

Classification of Cancerous Growths.

In order to determine how the stage of the disease at the time of operation influences the subsequent history of the patient it is necessary to devise some classification of cancerous growths. None with which I am familiar is entirely satisfactory, and I therefore made a very crude division of them into five groups. (1) A small nodule less than a walnut in size and without cutaneous involvement, or at most slight dimpling on picking up the skin. No clinical (glandular) metastasis. (2) A nodule larger than a walnut in size, with definite skin involvement, but no palpable glandular enlargement. (3) A small nodule as (1), but with palpable axillary glands secondary to it. (4) A large nodule as (2), but with metastases in the glands of axilla or neck. (5) A large ulcerating tumour with glandular extension.

The fallacies of this grouping are very obvious, but not more so than those of any other classification so far devised. In the first place, the size is no criterion whether the tumour is early or late from a pathological point of view. In the second place, axillary glands may be infected, but not palpable; in many cases the fact was noted that the patient was so stout that no useful palpation of the axilla was possible. It seems, however, justifiable to assume that, as a rule, a case without demonstrable glandular infection is in a pathologically earlier stage of development than one in which such infection can be clinically determined.

Type of Operation.

Many of the cases which form the basis of the following statistics underwent more than one operation. In one case after one breast was removed the second was found infected, and that, too, was later removed. In a few local recurrence made its appearance and a second or even third operation was performed to remove it. In all such cases the period of survival is measured from the date of the first operation until death.

To enter into details of the operation performed is no part of my present purpose. The series contains cases operated upon by many different surgeons, and probably no two of them adopted exactly the same technique. In practically every case, however, an attempt was made at radical excision. In one case a local excision of the mass was effected as a preliminary measure, the diagnosis being in doubt. Although microscopical examination proved the mass malignant, the patient refused further surgical treatment and was alive and well in June, 1924. Apart from an isolated case of this kind the scope of operation was always extensive, but its exact boundaries varied considerably. In nearly half the whole breast was removed with a wide area of skin and the sternal portion of the pectoralis major with its fascia. Sometimes the pectoralis minor was removed. A certain amount of the axillary fascia was dissected out, but no attempt made to clear the space or clear the vessels. In the remainder the axillary dissection was complete. In many the incision was carried down into the anterior abdominal wall and part of the muscular fascia removed. So far as I can determine, the supraclavicular glands were not in any case excised, but it is often impossible to discover from the notes precisely what was done in any particular case, so that no estimate can be made of the length of life after the various types of operation.

The following tables give an analysis of 465 cases—i.e., all the cases traced with the exception of 11, the date of whose death I failed to discover.

TABLE III.—*The Survival Rate.*

73 cases in Group 1 : still alive 19 (26 %)
58 ,, ,, ,, 2 : ,, ,, 6 (10 %)
162 ,, ,, ,, 3 : ,, ,, 10 (6 %)
132 ,, ,, ,, 4 : ,, ,, 8 (6 %)
40 ,, ,, ,, 5 : ,, ,, 2 (5 %)
465 ,, ,, ,, 45 (9 %)

It is important to know what is the probability that the diagnosis of these cases is correct. In 38 of the 45 the malignant nature of the growth was confirmed microscopically (all were carcinoma); in two cases the pathologist reported the histological appearance as "suspicious"; while in the remainder (five cases) no record of pathological examination can be found. Further, of all the cases which survived ten or more years after operation histological examination proved the lesion to be malignant in 61, but in 20 no record is available.

TABLE IV.—*Duration of Life After Operation.*

Including those cases still living, it is found that :—

54 cases in Group 1 } survived an average of { 5·6 years.
52 ,, ,, ,, 2 3·5 ,,
152 ,, ,, ,, 3 4·3 ,,
124 ,, ,, ,, 4 2·3 ,,
38 ,, ,, ,, 5 2·6 ,,

It appears, therefore, that, amongst other factors probably, the presence or absence of glandular involvement is of the utmost importance and its absence (even if clinical only) very materially improves the outlook. These figures are represented graphically in the diagrams (Figs. 1 to 6). The graphs represent the period of survival after operation.

The next point is the influence of the patient's age upon the result of surgical treatment. Is the disease more malignant and less amenable to operation in a young person than in an elderly or old ? Reference to Table V. shows that in each of the five groups the period of survival does not materially vary with the age of the patient, and taking all the groups together the same result is obtained. From these figures there is no evidence whatever that the age of the patient affects the prognosis or that cancer tends to be more malignant in the earlier decades of life than in the later.

Conclusions.

1. That if cancer is primarily a local disease and it may therefore be said that when local it is early, whatever the size or exact histological nature of the tumour, while it is late as soon as it reaches the lymphatic glands; then the earlier the disease at the time of operation the greater the possibility of completely eradicating it. The very earliest glandular infection enormously reduces the chances of cure.

2. The actual average duration of life after operation shown in Table V. is 4·6 years, but since some (9 per cent.) of the patients are still alive, and others (9 per cent. again) died of diseases other than cancer it is certain that the true average, qua cancer, is more than this, and probably approximates to five years.

3. The average duration of life *after operation* is greater by two years than that of unoperated cases

from onset to death. (The normal duration of unoperated cases averages three years.[1])

4. The age of the patient does not influence, one way or the other, the prognosis as regards ultimate survival after operation.

Clinical and Laboratory Notes.

A CASE OF RECURRENT PNEUMOTHORAX.

By L. T. Burra, M.D. Oxf.,
TUBERCULOSIS OFFICER, BUCKS COUNTY COUNCIL.

The following case is of interest as one in which there was recovery from pneumothorax, with a liquid effusion, and a recurrence of the condition about five years later with fatal issue :—

C. B., aged 31, enlisted in 1908, and was discharged from the army suffering from pulmonary tuberculosis in February, 1919.

History.—He first came under my notice in September, 1921, when he gave the following history. In November, 1918, while interned in Holland, he complained of pain in the right side of the chest and shortness of breath. Soon afterwards he was sent home, and pulmonary tuberculosis being diagnosed he was sent to the Brompton Hospital and afterwards to the Sanatorium at Frimley.

Condition on Examination.—When I examined him in September, 1921, he was in good general condition and the physical signs suggested quiescent disease of the upper part of the upper and lower lobes of the right lung with thickened pleura at the base—there was nothing suggesting pneumothorax; the left lung was free from abnormal signs. He came to one of the dispensaries at intervals, and showed a steady improvement in general health and in the condition of the lung, the symptoms and signs becoming less marked till Oct. 6th, 1923, when I was sent for urgently to see him at home. He was in bed complaining of pain in the right side of the chest for the past four days, with shortness of breath. He was lying down and was not in obvious distress—pulse 112, temperature 102·4° F. On examination I found typical signs of pneumothorax with a liquid effusion at the base. I explained the condition to him and he then said he had the same thing when first ill in November, 1918.

A few days later he was coughing up offensive purulent sputum, and two pints of offensive pus were withdrawn from the right pleura. This pus was swarming with T.B. He coughed up pus whenever the fluid reached the level of the sixth rib, and as he was losing ground and developed broncho-pneumonia of the left lower lobe, he was admitted to St. Bartholomew's Hospital. No operation for draining the pleura was undertaken owing to the condition of the left lung, but a considerable quantity of pus was drawn off by aspiration on one or two occasions; this pus did not show T.B. on examination.

He went down hill rapidly, and died about six weeks after the onset of the acute illness in October.

Post-mortem Examination.—At autopsy a complete pneumothorax was found on the right side with a perforation in the lower part of the upper lobe, and on the left side a recent widespread tuberculous broncho-pneumonia, presumably due to inhalation of pus from the right pleura.

In order to confirm the history of a previous pneumothorax, I wrote to Dr. J. F. Alexander, under whose care he had been in 1919; and in answer he wrote : "I remember C. B. well . . . . He had very definite signs of pneumothorax when I first saw him, coin sound, tinkling, and succussion splash. There was a lot of fluid at first, but this was gradually absorbed and before he left here there were no definite signs of pneumothorax . . . . There is no doubt about the previous pneumothorax."

I have only seen two papers referring to recurrent pneumothorax, both in the *Boston Medical Journal*,[2] but in the cases there recorded the condition seems to have been localised. Dr. Hyman Morrison, in his paper, quotes papers by Hamman (1916) referring to 16 cases, and by Marshall and Craighead (1918) referring to 43 cases; so that the condition apparently is not very uncommon.

I am indebted to Dr. Morley Fletcher, under whose care at St. Bartholomew's Hospital the patient was, for his permission to publish this note and for information as to the findings post mortem; and to Dr. Alexander for his description of the condition of his patient in 1919.

A NOTE ON THE TREATMENT OF PSORIASIS.

By Edward C. B. Ibotson, M.D. Lond.

Psoriasis remains a conundrum as to its ætiology, occurring as it does at all ages and often in people in apparently robust health. Viewed in the light of the cutaneous disturbances that occur in myxœdema and the improvement frequently produced by thyroid extracts, one cannot but feel that endocrine disturbance plays a great part in it. When in association with rheumatoid arthritis one feels that it is a case then of combined toxis and defective internal secretion. That it sometimes terminates in cancer cannot be wondered at when one considers that the old stock treatment consisted in prolonged and increasing administration of arsenic. The following case illustrates the success sometimes rapidly attained by the use of thyroid extract internally combined with the external use of tar :—

Case 1.—A recently married woman, aged 52, in apparently robust health, had had bad psoriasis for seven years, commencing at the age of 47. Her periods ceased only three years ago, so there was no connexion between their cessation and the onset of psoriasis. Her father, who died at the age of 85, had suffered from eczema but not from gout; one of his brothers had also suffered from eczema; paternal aunt died aged 85; uncle died aged 80; grandmother, mother's side, died aged 92; mother living, aged 72, never had any skin lesion but suffered from rheumatism; one sister living, one died at 15 of phthisis.

The patient, whom I first saw on August 28th, was tall, well-built, with healthy complexion, had never had any acute illness save the infantile complaints, measles and varicella, and had never been constipated. All vital organs working well; urine normal. She was much distressed by inveterate psoriasis, for which she had been previously treated by other medical men. Internally she had taken arsenic for long periods in increasing doses; also salicin and salicylate of soda. Externally she had had chrysarobin, salicylic acid, white precipitate, resorcin, and collodion. Nothing had done any good. Thyroid had not been tried.

Treatment.—I recommended her to reduce her diet to the minimum of meat and to live as much as possible on fish, fruit, vegetables, eggs, and milk. This was in view of thyroid treatment, which is considered to act more beneficially when little or no meat is taken. I put her on thyroid extract gr. i. (Burroughs and Wellcome) three times a day to be taken for three weeks; this was stopped for a week and then again resumed. I advised free purgation with Carlsbad salt. Externally she was to wash all the patches with warm water and soft soap twice a day to remove scales and then apply Hutchinson's paint, which consists of equal parts of liq. carbonis detergens, spirit vini rect., and liq. plumbi. subacet. B.P. She was also to wash the patches occasionally with ichthyol soap.

On August 28th there were large patches on the left elbow, front and back of both thighs, both knees, and front of both legs, on the lumbar spinal region, one on each hip, and one under the right ribs. There was also psoriasis of the nails of both hands. By Sept. 30th, under this treatment, all the patches had disappeared. The nails are still thin and are being treated with unguent. hydrargyri oxid. flav. The thyroid has been taken without any ill-effects, the pulse remaining absolutely normal.

Oct. 15th, 1924: The patient has continued on vegetarian diet and 3 gr. daily of thyroid extract. The skin remains absolutely clear and the diseased nails are beginning to be replaced by healthy ones. For them she has used ung. stanni. oleatis, ʒi to ℥i, as recommended by Dr. R. W. MacKenna,[1] of Liverpool.

April 8th, 1925: The patient remains free from patches, but she has had some red spots on the skin which disappeared after the application of scarlet red ointment. She also complains of dryness of the hair. This has ceased under pilocarpine and lanoline inunction.

May 20th: She remains quite free from psoriasis.

---

[1] MacKenna: Diseases of the Skin. Baillière.

I had another curious case illustrating the association of psoriasis and rheumatic fever.

CASE 2.—M. J., male, aged 35, came to me with psoriasis on Jan. 13th, 1921. Five days later he developed rheumatic fever and had a long illness. He came again to me on Dec. 1st, 1924, with psoriasis. I gave him an arsenical mixture, and on Dec. 3rd I was sent for to see him with rheumatic fever (temperature 102° F.).

April 8th, 1925: His temperature has long been normal, but he has pain in the shoulders. The psoriasis has not recurred.

The impression left on my mind is that if psoriasis be not an endocrine deficiency disease it is hard to explain in any other light.[2] I would be glad to hear the experience of others as to success with thyroid in psoriasis and as to recurrences.

Merioneth, N. Wales.

Medical Societies.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.

FILTERABLE VIRUSES.

THE fifth of a course of lectures on Pathological Research in its Relation to Medicine was delivered at St. Mary's Hospital Institute of Pathology and Research on May 28th, when Dr. W. E. GYE dealt with the filterable viruses. In his opening remarks the lecturer dealt with the history of these substances, remarking that some 40 or 50 diseases of animals were now ascribed to their activity with a fair measure of certainty. Among the human diseases included in the list were small-pox, chicken-pox, measles, and encephalitis lethargica. Of the large list of animal diseases, which included distemper, foot-and-mouth disease, rinderpest, and swine fever, he regarded pleuro-pneumonia of cattle and chicken plague as the only two in which the claim for the filtrable virus had been really substantiated. He described the difficulties with which the bacteriologist has to deal when attempting to investigate these organisms, owing to their minute size, about 0·15 of a micron, their hazy outline, and the impossibility of seeing them with ordinary microscopes. One theory put forward as to their nature was that they were liquids and living things at that; this was based on their ability to penetrate to the deeper layers of an agar plate. In the lecturer's opinion however, all the evidence pointed to their being living particulate organisms with nothing very mysterious about them; it was only their small size and the difficulty in their cultivation which stood in the way of their proper classification. Dr. Gye's own work in this matter had been concerned with the first of the three transmissible tumours described by Peyton Rous of the Rockefeller Institute in New York in 1911. This was a very loosely arranged spindle-celled sarcoma of the chicken possessing certain properties distinctive from all other similar tumours in that it was transmissible by a filtrate. It was also extremely specific, the experimental animals requiring at first to be related by blood to that in which the tumour originated. It was found that if this tumour were ground up, filtered through layers of sand and paper pulp, and passed through a candle, the resulting filtrate was capable of reproducing an identical tumour on injection into another bird. Dr. Gye, experimenting with this tumour, found that 1 c.cm. of the filtrate, which is singularly free, to all appearance, of any particulate matter, would produce a small, hard point under the skin at the side of inoculation in seven days, while in three weeks the bird had usually died with widely distributed metastases. Curiously, these secondary growths frequently occurred in the heart muscle. If one-quarter of a c.cm. of the filtrate were used with three-quarters of a c.cm. of Ringer solution to make up the total quantity, the resulting tumour appeared much later, if at all, so that the size of the tumour, within certain limits, was proportional to the amount of filtrate injected. He pointed out the objections to the use of the term "filterable virus," based on the fact that the filtrability of a substance depended on many conditions, such as the pressure, the time, and the presence of mucin and nucleo-proteins.

The next experiment was performed to determine whether or not there were anything particulate in this filtrate. It was centrifugalised at the rate of 9000 revolutions for two hours. It was then found that the inoculation of 1 c.cm. of the upper portion produced tumour growth after a slightly longer interval than did the inoculation of the lower portion from the centrifugalised tube. There thus appeared to be some evidence in favour of the presence of a particulate substance. If the supernatant fluid of a growth of the virus in sugar were treated in the same way there was very definite evidence to this effect, as the upper portion of the fluid then produced no tumour or only a very small one after a considerable interval, by which time the tumour produced by the inoculation of fluid from the bottom of the tube had attained a considerable size. The objection to be raised to this result was the possibility of masses of colloidal material being spun to the bottom of the tube and dragging the virus with them. In a further experiment some of the tumour filtrate had its pH reduced to 4·5 with acid phosphate, with similar results on centrifugalising. It thus appeared that there was sufficient evidence to justify the conclusion that the virus was particulate. If portions of the tumour were centrifugalised in Ringer solution a small amount of fluffy material would appear in the bottom of the tube. The supernatant fluid was carefully pipetted off this and it was then washed with two centrifugalisations with Ringer. The final deposit, when diluted with 1 c.cm. of Ringer, produced no tumour when inoculated into a chicken.

The dominant characteristic of the three tumours investigated by Rous was their peculiar specificity. The final experiments described by Dr. Gye were undertaken in an attempt to show that the specificity could not depend on the virus itself; it must be accompanied by something else which determined the specificity of the infection. If the filtrate were carefully mixed with chloroform and heated at 37° C. for three or four hours and the chloroform then removed by a pump, the inoculation of 5 c.cm. of the resulting filtrate produced no tumour, although less than 1 c.cm. of the original would have killed the bird. If pieces of tumour were dropped into culture medium and incubated for three days aerobically the culture fluid did not produce tumour formation. If, on the other hand, the benign fluids resulting from the two last experiments were mixed and inoculated a tumour resulted. Thus there appeared to be two elements in the filterable virus of this condition, a non-particulate portion and a particulate, living portion, invisible with ordinary microscopes. The proof that this was a virus depended on its cultivation, and this had been successfully done.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of this Society was held in the Royal Infirmary on May 13th, Sir DAVID WALLACE, the President, in the chair.

Exhibition of Cases.

Three cases were shown for Dr. CHALMERS WATSON. The first was of a man suffering from disseminated sclerosis; an X-ray examination demonstrated ileocolic stasis, and he had marked bacilluria. During treatment he developed acute appendicular symptoms with a recurrence of the symptoms of disseminated sclerosis, which had abated under intestinal treatment.

---

[2] Evolutionists might consider psoriasis a reversion to the fish or lizard type.

The second case was a man with an old specific history, who had been treated for sclerosis of the cord 11 years ago. A year ago he had an acute attack of nephritis, and while in bed his legs became gradually drawn up; there were marked ileal stasis and bacilluria. A third case of disseminated sclerosis had advanced oral sepsis. It was suggested that a toxin might be a cause of the sclerosis, and treatment was by an autogenous vaccine.

Mr. J. W. STRUTHERS showed a woman, aged 49, in whom a tumour had been removed from the jaw in 1916, who had returned with a swelling in front of the left tibia. On examination further tumours were found on both femurs. The tibial tumour, a myeloma, was removed easily; the surface growth was large, but it had a comparatively small extent in the medullary cavity. It was remarked that these so-called giant-celled tumours are often a feature of osteitis fibrosa and that they were probably local manifestations of the disease. Another case was shown which had been operated on a long time previously for a fatty tumour of the thigh; more recently four further operations had been carried out on the tumour as it recurred, finally as a fibroid sarcoma; this was interesting, said Mr. Struthers, as a fatty tumour is the only tumour which is supposed never to undergo malignant transformation.

Prof. D. P. D. WILKIE showed a man, aged 44, suffering from an arteriovenous aneurysm, caused presumably by a fragment from a bursting rifle grenade. After being a prisoner of war he went to Switzerland, where a swelling in his neck was noticed together with a bruit. He was discharged from the army. When now examined, he had obvious pulsatile swelling in the left side of the neck and prominence of the eye on that side with marked bruit over the swelling. On operation the vessels involved were found to be the common carotid artery and the jugular vein, the communication being of no great size, stout catgut was tied round the communication, leaving a lumen to both artery and vein. Immediately after tying the suture all buzzing ceased, and since then the eye had receded and symptoms had disappeared.

Mr. HENRY WADE presented a case of a pensioner suffering from tuberculous disease, involving the first and second lumbar vertebræ with a large psoas abscess on the right side; after due consideration it was decided to perform Albee's operation for fixation of the spine. A graft of about 10 inches was taken from the tibia and implanted from the tenth dorsal to the fourth lumbar spines; a plaster jacket was put on and left for three months, during which the psoas abscess was treated by aspiration. The patient now, after six months, was comfortable and walking about, whereas under more conservative treatment he would have had to spend two years in bed.

Mr. W. STUART showed a case of Dupuytren's contracture, where marked improvement had followed 14 injections of fibrolysin; the fingers were for all practical purposes fully extended. In his experience injections of fibrolysin gave better results than any other method; in a certain percentage of cases marked improvement resulted, but the method was uncertain. The injections must be into the palm, when given into deltoid or buttock he had had no success.

Mr. GEORGE CHIENE showed a case of carcinoma of the appendix in a man of 26; the disease was not deep-seated and it was a question whether a further operation should be done. A similar case in a woman operated on ten years ago had given no further trouble.

Mr. JAMES GRAHAM showed a case of an elderly man who seven years ago had suffered for two years from hæmaturia without symptoms other than anæmia; cystoscopy showed the blood to come from the left ureter, the right functioning normally; fearing the presence of a tumour the left kidney was removed. Lately a similar hæmaturia arose from the remaining kidney; this was examined and found to be affected by chronic interstitial nephritis, distinct but not marked with a thickened capsule. Decapsulation was performed, shortly after which the hæmaturia disappeared. The case was interesting, as it emphasised the fact that interstitial nephritis might be associated with profuse hæmaturia without other symptoms and that an apparently normal kidney with hæmaturia may be associated with pathological changes.

Dr. DOUGLAS GUTHRIE demonstrated a patient with early malignant disease of the vocal cord, which had been removed by laryngo-fissure. Local and general anæsthetics were used, the skin was injected with novocaine tinged with stain, tracheotomy was performed, and the larynx anæsthetised. The cough reflex was abolished and the growth removed with ease. A speedy recovery followed, and at the time of demonstration, ten weeks after, the patient had a good voice produced by fibrous tissue in place of the excised cord.

Mr. W. A. COCHRANE showed a case of a man aged 24 who was admitted to hospital as an "acute abdomen." On exploration two huge tumours of the size of oranges were found in the pelvis, which proved to be two separate foci of tuberculosis of the small intestine; a resection was performed and the patient made a good recovery. The tumours were of a hyperplastic nature rarely found in the small intestine.

Dr. JOHN D. COMRIE showed three cases illustrative of mental disturbances in neural syphilis. All showed strongly positive Wassermann reactions, and all improved under N.A.B., sulpharsenol or neo-silver-salvarsan, respectively.

Mr. W. QUARRY WOOD showed two cases in which bone cavities had been filled with muscle grafts. The first was in the case of a youth aged 19 with relapsing osteomyelitis of the tibia; the bone cavity was purified and filled by a muscle flap. The second case was of a similar condition in a man of 25, who had suffered for 14 years from osteomyelitis of the humerus. This was treated in the same way. In both cases excellent results had been obtained.

THE remarks attributed to Dr. G. W. Mitchell in the discussion on High Voltage and Radio-therapy, held at the Royal Society of Medicine (May 30th, p. 1131), were made by Dr. William Mitchell, of Bradford.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 1136.)

EVIDENCE OF THE BRITISH MEDICAL ASSOCIATION.

THE statement of evidence now printed as Appendix XLVII. has already been summarised in our issue of May 9th, p. 993.

It was supported in oral examination by Dr. R. A. Bolam, Chairman of the Council; Dr. H. B. Brackenbury, Chairman of the Representative Body; Dr. H. Guy Dain, Chairman of the Insurance Acts Committee of the Association, and Dr. A. Cox, Medical Secretary. Supplementary evidence was given on certain points by Dr. H. J. Cardale, Chairman of the London Panel Committee; Mr. N. Bishop Harman,

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6).

Honorary Treasurer of the Association, and Dr. Stanley Hodgson, Chairman of the Salford Panel Committee.

(Q. 14605.) At the outset the representative character of the evidence was made clear, Dr. Brackenbury stating that there were only two main points upon which there was any difference of opinion. One was with regard to the inclusion of dependants in an insurance scheme, some considering it doubtful whether they should be included even on the restricted basis set out in the Memorandum, while others, a minority, regarded their inclusion as a matter of urgency. The other point was with regard to the question of an appeal to the courts of law, a considerable minority holding the view that there should be such an appeal on all grounds instead of on some only as proposed in the statement of evidence.

(Q. 14607–8.) Generally, the recommendations would be found to be in the direction of continuance of the present scheme with contractions in certain directions and extensions in others, considerable stress being laid on establishing and strengthening the relationship of such a scheme to the other health services, public and voluntary.

An Improved Atmosphere and an Improved Health.

(Q. 14612–20.) The panel service is working in an improved atmosphere. Doctors are coming on the panel in increasing numbers, and where in the profession there was formerly active antagonism in certain quarters, this has resolved itself into indifference. On the insured person's side, Dr. Brackenbury said :—

> (Q. 14612.) We have, as general practitioners, the almost universal experience that insured persons are much more willing to come to us and to take advantage of their opportunities instead of exhibiting prejudice or making the remark that they came unwillingly.

Insured persons seek advice in the early stages of disease, and this is directly preventive in its effects. The gain to the comfort of the individual in knowing that he can have medical attention whenever he needs it, and sickness benefit experience which points to a reduction in national sickness, both mean a considerable gain in the national health. As to the quality of the service, Dr. Brackenbury said that there was no truth in the statements made that the panel service was an inferior one.

> (Q. 14621.) Do you think that the insurance practitioners as a class give their professional best to the insured persons, though such service is given under a contract and paid by capitation and is under a certain degree of State regulation ?—In spite of those three things I am sure it is a fact that each doctor in relation to his own patients does give of his professional best.

Dr. Cox added to this that the insurance system had given the medical profession itself a greater control over the service than it ever had before under any collective system, and this had given it an increased interest in the success of the system.

Complaints as to the London Service.

(Q. 14623–14654.) On a question here interposed by Sir Humphry Rolleston as to statements made to the Commission that in London there were more complaints about the service than elsewhere, Dr. Cardale said that in 1924 there were only 87 formal complaints as compared with about 7 million attendances—a quite insignificant fraction. Apart from formal complaints, Dr. Cardale suggested that much prejudice was created in London in regard to the service by occasional press stunts, and this was emphasised by Dr. Cox, who stated that there had always been a section of the press who would do almost anything to damage the Insurance Act. He instanced a visit to an editor to urge him to publish a letter which he had prepared in reply to a very damaging attack, and eventually extracts from Dr. Cox's letter appeared in such a way as to give a wrong impression. The editor told him quite deliberately : "You must remember we are not out to help to defend the Act ; we are out to try to kill it."

Dr. Brackenbury pointed out that London and Edinburgh were very largely the centres of organised or expressed antagonism to the Act at the beginning, and that there was still a lower proportion of general practitioners doing insurance work in those places than elsewhere. To be perfectly fair Dr. Brackenbury added that :—

> (Q. 14653.) One must say that in the poorer parts of London there is a tendency sometimes, by no means always, and only in a minority of cases, to get a doctor who is himself a bird of passage there.

He also said :—

> We may have many insured persons concentrated much more largely than in any other place who are clerical workers or insured persons who are on the margin and who, in a few years' time, will be going out of insurance, and we find that that is the class of person who complains more about the working of the Act than any other, not really from facts but from prejudice, impressions derived from second-hand sources if you like. I think you will find amongst the real industrial population that there is no more feeling in London than there is elsewhere.

Persons to be Provided for.

(Q. 14671–2.) The number of general practitioners doing insurance work in relation to those not on the panel is roughly 3 to 2, the numbers being estimated at 14,700 and 10,000 respectively.

(Q. 14666.) As evidence of the extra work thrown on the insurance practitioner, Dr. Cox referred to the Plender Report issued when the Insurance Bill was being prepared in 1911, which showed that the average number of attendances on the population in certain industrial areas was 1·33 per year, whereas the insured person now gets not less than 3·75 attendances. For this reason amongst others it would appear that there must be some line of demarcation within the insurance scheme so that it should be available (Q. 14689) only for those persons who would be unable to obtain it without the help of that scheme. The application of this principle involves the question of a broad income limit.

> (Q. 14692.) In the public provision of education we have no such criterion. The public elementary schools are open to all, irrespective of income. Do you not think there is a parallel here ?—No. I think it is a false parallel altogether. There would be a parallel if it is considered that the State ought to have full control of the provision of education on the one hand, and full control of the individual's health on the other, but we are presupposing that it is to be done by means of a contributory insurance scheme. If it is to be done by means of a contributory insurance scheme there is no parallel at all.

Correspondence to Private Practice.

(Q. 14710–14724.) With regard to the principle laid down in the Memorandum that the conditions of the insurance medical service should approximate as nearly as possible to those of private practice, Dr. Brackenbury said that they were in a condition of apprehension for the future rather than criticising the working of the scheme in the past. Among the really important things in this connexion was the individual relationship between the doctor and his patient.

> (Q. 14710.) Anything that encroaches upon the confidential individual relationship between doctor and patient we view with suspicion and with the feeling that it will, though it may have some other advantages which we are perfectly prepared to consider, destroy or tend to destroy what we believe to be one of the fundamental things that enables us to do the good work which we hope we are doing.

In later evidence Dr. Brackenbury pointed out that with one exception—

> (Q. 15213.) The contract and relationship between the doctor and the patient is the same in insurance practice as in private practice. In private practice there is, though not a written, a perfectly legal contractual relationship between the doctor and the patient. The doctor undertakes to devote his utmost skill and care to the attention of the patient, and if he does not do it the patient can sue him at law. There is, therefore, a definite legal contractual relationship, though unwritten, between doctor and patient.

In private practice, it is true that a doctor has a right to refuse to attend an applicant even in an emergency. Under the insurance system he has no such right,

> so that with that one exception, which is after all scarcely an exception at all, because it is merely putting into a contract what is habitually done from motives of humanity, the relationship between doctor and patient is exactly the same whether under the insurance system or otherwise.

In regard to free choice of doctor, Dr. Cox said that this was not a fetish, but a fundamental of human nature.

> (Q. 14717.) I have never yet myself met any individual who would not object very strongly to being told that he could not have his own choice—whether it was foolish or not—in the matter of a doctor. In fact, there are some people who are so foolish as to want to choose their own tailor or their own Member of Parliament, or other things which are much less important.

The Objection to Clinics and to a State Medical Service.

In explanation of their objections to a system of clinics the witnesses said that they had in mind premises staffed by a limited number of persons, and limited to a certain extent of practice. In certain rural areas and in certain densely populated industrial areas it might be convenient to have a common consulting-room and surgery at the same premises rather than have the poor rooms which doctors in those poor areas can manage to obtain.

> (Q. 14720.) We have no objection to the premises as such in cases where it seems desirable to provide them, provided the other circumstances can remain the same, that is to say, that every doctor can have access to them for his own patients and that any patient is not obliged to be attended by a particular doctor.

Clinics, however, as generally understood, diminished freedom of choice and moved away from the intimate individual relationship of doctor and patient towards a State medical service.

On this question generally Dr. Bolam said :—

> (Q. 14779.) May I say, as one who is not an insurance doctor, that the feeling in the profession is that the prime relationship should be between the doctor and the individual, and not between the doctor and a Government department, or any lay body. That is the essence of the whole matter. . . . In the case of a purely whole-time State-salaried medical service there is not the incentive to deserve the confidence of the individual. The effort is . . . directed rather in other channels.

Questioned as to the possibility of a national medical service permitting of a choice of doctor, Dr. Brackenbury replied :—

> (Q. 14767.) If you can elaborate a National Health service scheme which will give as great freedom of choice to the individual patient as exists under the present circumstances, of course that objection falls to the ground ; but we have not seen any approach to that in any national scheme.

Surgery Accommodation.

(Q. 14741–3.) Complaints as to surgery and waiting-room accommodation have been very few and not very important.

> They really came largely during the tremendous influenza epidemic of 1918 when there were people who had to wait even outside to see the doctor, because there was no room in the waiting-room. You cannot make in private houses or in surgeries, or even in institutions, complete provision which would always cover the biggest emergency.

In some crowded areas there are actual physical and structural difficulties in improving the accommodation, and the inconvenience is felt equally by private and insurance patients.

A Bias Towards Prevention.

(Q. 14752.) As illustrations of the bias towards prevention in insurance practice, cases were quoted of an insurance practitioner who sought out his patients during an influenza epidemic and offered them preventive inoculation, and of another delivering health lectures to his patients.

(Q. 14828.) This bias towards prevention was cited later as the principal advantage of a capitation system of payment as compared with that of payment by attendance, where there must be a bias away from prevention and in the direction of multiplying attendances.

(*To be continued.*)

THE GENERAL MEDICAL COUNCIL.

SUMMER SESSION.

Penal Cases.

Eighteen penal cases came before the Council during the session. The cases were heard in public ; the Council deliberated on them in camera, and the results were publicly announced as usual.

Tuesday, May 26th.

Cases Reported by the Dental Board.

The following cases were reported by the Dental Board of the United Kingdom to the General Medical Council.

The Case of John Begg, registered on Dec. 3rd, 1904, as of 11, Montgomery-street, Edinburgh, L.D.S.R.C.S. Edin., 1901, was considered by the Dental Board on May 12th. Mr. Begg had been convicted at the Edinburgh police-court on three occasions for drunkenness, and the Board found that his name ought to be erased from the Dentists Register. The Council considered the case and remitted it back to the Dental Board for further inquiry and report.

The Case of Samuel Robertson Crosbie, registered on March 3rd, 1923, as of 21, Hamilton-street, Camden Town, London, N.W. 1, "Dentist, 1921" was considered by the Dental Board of the United Kingdom on May 12th. The Dental Board, having considered the conviction against Mr. Crosbie, reported as follows : On May 12th, 1925, the said Samuel Robertson Crosbie attended before the Board, and was duly heard. Mr. Crosbie asked for an adjournment for three months or until the next session of the Board, on the ground that he hoped to have his case reopened in the Court of Criminal Appeal or by the Home Secretary. Mr. Crosbie had been convicted at the Essex Quarter Sessions held at Chelmsford on Jan. 2nd, 1924, of embezzlement and fraud and had been sentenced to 12 months' imprisonment with hard labour. The Dental Board found that his name ought to be erased from the Dentists Register. The Council directed that it be erased.

The Case of James Gray, registered on June 25th, 1924, as of 16, Eglinton-street, Belfast, "Dentist, 1921," was considered. The Dental Board reported that Mr. Gray had systematically canvassed in Belfast for patients by personal visits and by employing an agent or agents to canvass on his behalf. The Board found that his name ought to be erased from the Dentists Register. The Council directed that it be erased.

The following cases concerning medical practitioners were considered by the Council.

The Case of Shridhar Bheekajee Gadgil.—This practitioner, registered as c/o Nat. Bk. of India, Fort, Bombay, L.M.S. U. Bombay, 1898 ; M. 1900, F. 1915, R.C.S. Eng. ; L.R.C.P. Lond., 1900, whose case was adjourned from May 28th, 1924, had been convicted on Sept. 21st, 1923, and fined for insulting behaviour. Dr. Gadgil was present accompanied by Mr. Oswald Hempson, his solicitor. The President stated that Dr. Gadgil could not be tendered as a witness as the Council had already decided that the conviction had been proved. Further letters of recommendation from Dr. Gadgil's professional brethren were put in. The Council decided not to erase Dr. Gadgil's name from the Medical Register.

The Cases of John Joseph Brennan and Vivian Thomas Pearce Webster.—The case of John Joseph Brennan, registered as of Maeryrhaf, The Walk, Merthyr Tydfil, L.R.C.P. Edin., 1892 ; L.R.C.S. Edin., 1892 ; L.F.P.S. Glasg., 1892, had been adjourned from Nov. 27th, 1924. Dr. Brennan had been charged with signing and issuing a medical certificate, dated March 26th, 1924, which was "untrue, misleading, or improper." Vivian Thomas Pearce Webster, registered as of Tygwyn, Merthyr Tydfil, M.R.C.S. Eng., 1910 ; L.R.C.P. Lond., 1910, had a similar charge laid against him. His case had also been adjourned from Nov. 27th, 1924. As both these practitioners had been warned at the last session of the Council as to the gravity of lax certification, and having regard to their conduct since the last hearing, the Council did not see fit to erase their names from the Register.

The Case of Henry Love, registered as of Avoca, Mitcham, Surrey, M.B., U. Dub., 1878; L.R.C.S. Irel., 1878, adjourned from May 28th, 1924, was that he had, in contravention of the Midwives Acts of 1902 and 1918, enabled uncertified women to act as midwives. The Council, having considered the evidence as to Dr. Love's conduct in the interval from his brother practitioners, did not see fit to erase his name from the Medical Register.

The Case of Henry Spencer Hughes, registered as of Galen House, Lozells-road, Birmingham, M.R.C.S. Eng., 1894; L.R.C.P. Lond., 1894, adjourned from May 30th, 1924, was next dealt with. He had been arraigned on a similar charge to the preceding case. The Council gave a decision as in the case of Dr. Love.

The Case of Nowroji Merwanji Tarachand, registered as of Mansfield, Nottingham, M.R.C.S. Eng., 1893; L.R.C.P. Lond., 1893, adjourned from May 28th, 1924, was concerned with signing National Health Insurance certificates in a misleading manner. The Council, taking into account Dr. Tarachand's assurance as to his future attitude as regards truthful and accurate certification, did not see fit to erase his name from the Medical Register.

WEDNESDAY, MAY 27TH.

The Case of Henry James Burke, M.C.—This practitioner, registered as of Ivy House, Hadfield, Derbyshire, L., L.M. 1913, R.C.P. Irel., L., L.M. 1913, R.C.S. Irel., had been convicted: (1) At the Glossop police-court of driving a motor-car in a manner dangerous to the public; (2) at the same police-court, of being drunk in charge of a motor-car; and (3) at the Mottram Petty Sessions, of being drunk in charge of a motor-car. Dr. Burke attended, and was accompanied by Mr. Whittingham, of Manchester, his solicitor, who put in testimonials from brother practitioners. These convictions were proved to the satisfaction of the Council, but judgment was postponed until May next, with the usual proviso as to character and conduct in the interval. The President commented on the significance of such convictions which indicated a habit that might be dangerous to a professional man, to the public, and to the patients under his charge.

The Case of Sureswar Sarkar.—This practitioner, registered as c/o Grindlay and Co., 54, Parliament-street, London, S.W. 1, L.R.C.P. Edin., 1907; L.R.C.S. Edin., 1907; L.F.P.S. Glasg., 1907; L.M.S.U. Calcutta, 1905, had been convicted at the Assizes held at Leeds on March 16th, 1925: (1) Of attempting at Sheffield in January, 1924, to rape Lilian May Potter; (2) of indecently assaulting her and like offences on other dates, of raping her and administering a drug to her with intent to stupefy in May 1924; and (3) of indecently assaulting Eva Potter in January, 1924. The sentence was five years' penal servitude. Dr. Sarkar did not attend in answer to his notice, nor was he represented. The Council directed the Registrar to erase Dr. Sarkar's name from the Medical Register.

The Case of John Edward Rees.—This practitioner, registered as of Glandwr, Tresaith, Cardiganshire, L.R.C.P. Edin., 1913; L.R.C.S. Edin., 1913; L.R.F.P.S. Glasg., 1913, had been convicted of the following misdemeanours, viz.:—(1) On April 5th, 1921, at the Lower Troedyram Petty Sessions (Cardigan) of being found drunk on the highway; (2) on May 15th, 1922, at the Cardigan Borough Petty Sessions of being found drunk on the highway in charge of a motor cycle; (3) on May 15th, 1922, at the Cardigan Borough Petty Sessions of being found drunk on licensed premises; (4) on Feb. 3rd, 1925, at the Newcastle-Emlyn Petty Sessions of being found drunk in charge of a motor car; (5) on Feb. 3rd, 1925, at the Newcastle-Emlyn Petty Sessions of driving a motor car on the highway in a manner dangerous to the public. Dr. Rees attended in answer to his notice, accompanied by Mr. Daniel Johns, his counsel, instructed by Mr. J. C. Williams, solicitor, of Carmarthen. Witnesses were called to testify as to Dr. Rees's character, and a petition signed in his district against his erasure from the Register was put in. Judgment was postponed until May next with the usual proviso as to character and conduct in the interval.

The Case of Albert Edward Woolfe Sandelson.—This practitioner, registered as of 347, Bury New-road, Higher Broughton, Manchester, L.A.H. Dub., 1923, had been summoned to appear before the Council on the instance of the Salford Local Medical and Panel Committee, it being charged against him that he had made certain false entries in his day-book with regard to a patient, Thomas Walter Lodge, under the Medical Benefit Regulations, 1924, for the purpose of claiming remuneration in respect of attendance on a patient from the Salford Insurance Committee. Dr. Sandelson attended in answer to his notice, accompanied by Mr. T. Eastham, K.C., with him Mr. Melville, his counsel, instructed by Gisborne and Co., solicitors. In the absence of a complainant the Council's solicitor placed the facts before the Council. He stated that the matter was brought to the notice of the Council by the Ministry of Health and put in a copy of the finding of the Salford Committee and other documents relative thereto. Mr. Eastham then addressed the Council on behalf of Dr. Sandelson, and read statutory declarations by Mrs. Lodge and her husband. These were in certain points at variance with the evidence they had given before the Salford Committee. The judgment of the Council was that the facts alleged against Dr. Sandelson had not been proved to the satisfaction of the Council.

THURSDAY, MAY 28TH.

The Case of Alex. John Douglas Cameron.—This practitioner, registered as of Adelaide House, Northampton, M.B., Ch.B., 1909, U. Aberd., was on Oct. 17th, 1924, convicted of unlawfully killing John Rowlatt Corner, and was sentenced to be imprisoned in the Second Division for nine calendar months. Dr. Cameron attended in answer to his notice, accompanied by Mr. Alex. Neilson, K.C., his counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors for the London and Counties Medical Protection Society. The Council's solicitor placed the facts before the Council. He put in the certificate of conviction and read extracts from the depositions at the trial. Mr. Neilson addressed the Council on behalf of Dr. Cameron, read nine statutory declarations testifying to the good character of Dr. Cameron, and put in a copy of the judge's summing-up at the trial. The Council decided not to erase Dr. Cameron's name from the Medical Register.

The Case of Sydney Edgar Price.—This practitioner, registered as of Dudley Port House, Dudley Port, Tipton, Staffs, L.R.C.P. Edin., 1899; L.R.C.S. Edin., 1899; L.F.P.S. Glasg., 1899, appeared on the following charge: That, being a registered medical practitioner, he was responsible for and, moreover, countenanced the issue to 11 patients of 32 misleading and improper National Health Insurance certificates, in that he allowed his clerk dispenser to sign and issue them in his (Dr. Price's) name and on his behalf. Particulars were then given. Dr. Price attended in answer to his notice, attended by Sir Henry Maddocks, K.C., his counsel, instructed by Mr. F. W. Green, solicitor, of Dudley. The Council's solicitor handed in the report of the Medical Services Subcommittee of the Staffordshire Insurance Committee. Sir Henry Maddocks tendered Dr. Price as a witness on his own behalf and examined him. Dr. Price was cross-examined by the Council's solicitor and answered questions put to him by the chair, by members of the Council through the chair, and by the legal assessor. In the course of the cross-examination of Dr. Price, it was elicited that Dr. Price had 2500 patients on his panel, for 700 of which he himself did the dispensing. During the month of January, 1925, Dr. Price's signature was attached to 140 insurance prescriptions, only one of which signatures he recognised as being his own. For the defence it was urged that Dr. Price's clerk had been with him for 16 years. The clerk had since died. The Council found the facts alleged against Dr. Price to have been proved, and the Registrar was directed to erase Dr. Price's name from the Medical Register.

The Case of Charles Nathaniel Barton.—This practitioner, registered as of 88, Redcliffe-gardens, South Kensington, London, S.W. 10, L.S.A. Lond., 1896; M.R.C.S. Eng., 1897; L.R.C.P. Lond., 1897, was arraigned on the charge of committing adultery with a married woman with whom and with whose family he stood in professional relationship, of which adultery he was found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Oct. 22nd, 1924, and made absolute on May 4th, 1925. Dr. Barton appeared in answer to his notice, accompanied by Mr. Oswald Hempson, his solicitor. The Council's solicitor placed the facts before the Council. He stated that the divorce case was not defended, but that Dr. Barton now denied professional relationship.

The hearing of this case was concluded on Friday, May 29th. The Council found that the facts alleged against Dr. Barton had not been proved to the satisfaction of the Council.

The Case of Austin Heron.—This practitioner, registered as of Mullindrait House, Stranorlar, Co. Donegal, L., L.M. 1924, R.C.P. Irel., L., L.M. 1924, R.C.S. Irel., had been convicted on Feb. 12th, 1925 (in the name of William Gallagher), at the Sutton Petty Sessions of "unlawfully, wilfully, openly, lewdly, and obscenely" exposing his person in a public highway with intent thereby to insult certain females. Dr. Heron appeared in answer to his notice. He was not accompanied by counsel or solicitor. The Council found that the conviction was proved to the Council's satisfaction, but judgment was postponed for a year with the usual proviso as to character and conduct in the interval.

FRIDAY, MAY 29TH.

The Case of Wilfred Edgar Levinson.—The case of W. E. Levinson, registered as of 5, College-road, Brighton, L.R.C.P. Lond., 1911; M.R.C.S. Eng., 1911, was considered on Friday afternoon and the hearing was continued on Saturday, May 30th. The hearing not being concluded by 1 P.M. on this day, the counsel moved an adjournment until June 4th, when the hearing of this case will be resumed.

REPORTS OF COMMITTEES AND OTHER BUSINESS.

Restorations to Register.

At a meeting of the Executive Committee on Monday, May 25th the Registrar reported that, the prescribed conditions having been duly fulfilled in each case, the names of the undermentioned persons had been restored to the Medical Register, from which they had been erased in conformity with the provisions of Section 14 of the Medical Act, 1858:—

Charles T. Andrew (S.), Edward V. Briscoe, Muljibhai K. Dalal (S.), Robert E. Cameron (S.), Stanley D. Craig (S.), Alban Dixon, John Holmes, Clermont Grantham-Hill, George F. Hulme (S.), Edward C. MacDermot (I.), Marion E. Mackenzie (S.), Farquhar McVean (S.), Leopoldo C. Mascarenhas, Arthur G. M. Middleton, Louis S. F. R. Norman (S.), Thomas M. O'Donnell (I.), Reginald F. M. Overton (I.), Hon. George H. Scott (S.), Henry A. Speed, and John Wreford.

S. = Scotland; I. = Ireland.

Reciprocity of Medical Practice.

As a result of the re-establishment of reciprocity of medical practice between Great Britain and Italy the Committee resolved to place on record their gratification at the satisfactory conclusion of this matter; and that the thanks of the Council be transmitted to the Privy Council, the Foreign Office, and the British Ambassador at Rome for their valuable assistance.

A letter was read from the Registrar of the College of Physicians and Surgeons of Province of Saskatchewan saying that there was no desire to retain British reciprocity if that involved inter-provincial reciprocity and reciprocity with countries other than Great Britain. It was never their intention that reciprocity should include any except bona-fide British graduates registered by the Council. A letter was written to Saskatchewan on March 21st, 1925, asking if the Council had met, and if they had any further observations on the subject to send. A reply was received, dated May 4th, stating that at the last meeting of the Council no further action was taken. They did not wish to terminate British reciprocity, in so far as bona-fide British graduates were concerned; but, if it meant indirect registration, this could not be agreed to. It was therefore resolved:—

That a communication be addressed to the Lord President, pointing out that as reciprocity between Saskatchewan and this country had ceased, owing to the recent change of the Provincial law, His Majesty in Council should be moved to rescind the Order in Council of 1915, applying Part II. of the Medical Act, 1886, to the Province of Saskatchewan.

With regard to reciprocity in New Brunswick, following several communications, it was resolved:—

That a further communication be addressed to the Council of Physicians and Surgeons of New Brunswick, pointing out that the General Council have no power to agree to their suggestions, and that, unless full reciprocity is maintained, the Council will be compelled to take the same action as in the case of Saskatchewan.

Indian Universities.

A communication was read from the India Office stating that Colonel R. A. Needham, C.I.E., I.M.S., had been reappointed to act as inspector on behalf of the Council. Reports by Colonel Needham in regard to the Universities of Bombay and Lucknow were presented to the Committee. It was resolved:—

(*a*) That under the same conditions as before, the recognition granted to the M.B., B.S. degrees of Bombay and Lucknow be continued till June 30th, 1926; (*b*) to inquire what are the relations between the Municipal College of Bombay and the University; the Lady Hardinge College, Delhi, and the University of Lahore; and the Vizagapatam College and the University of Madras.

Tanganyika.

A communication was read, dated Feb. 6th, 1925, from the Principal Medical Officer at Dar-es-Salaam, saying that the Government medical staff and the few private practitioners were inadequate for the wants of the country, and that the exclusion of medical aid from the native population was a policy that should be avoided as far as possible. He stated that an M.D. of Illinois, of the Lutheran Mission at Moshi, had applied for registration, and that sub-assistant surgeons, whose qualifications did not permit of registration, might be licensed while in Government service. It was suggested that the Principal Medical Officer or a board of three registered practitioners, one of whom should be the deputy P.M.O., might be empowered to use their discretion in licensing to practise such persons as they considered possessed suitable or sufficient medical qualifications for the purpose, keeping in view the limitation of their field of work, except in emergency, to the native population. By direction of the President the P.M.O. was informed that no objection would be made by the Council if, by an amendment to the ordinance, power were given to the proposed board of three to issue an annual licence to such persons as were named. The Committee approved the reply sent to the P.M.O.

South Australia.

At the meeting of the Committee on May 22nd, 1922, a communication was read from the South Australia Medical Board, calling attention to their Medical Act of 1921, in which it was prescribed, inter alia, that no registration fee should be payable by a person already registered in a country forming part of His Majesty's Dominions, if there were reciprocal arrangements in regard to the matter, and asking for its consideration by the Council. The Committee resolved :—

> (*a*) That the South Australian Medical Board be informed that the Medical Council has no power to discriminate between one class of registrable practitioners and any other in respect of original registration fees ; (*b*) that the Board be further informed that the Council has no power to levy an annual fee on registered practitioners in lieu of one commuted fee, as appears to be the case in South Australia.

A further communication was read, dated March 17th, 1925, from the South Australia Medical Board, suggesting that there was no actual legal difficulty in the way of effecting reciprocity of registration between Great Britain and the State of South Australia on payment of a nominal fee, and asking that the matter should once more receive consideration. It was resolved :—

> That the Committee adhere to their view of the English law as to their powers, and that they have nothing further to add to their previous resolution.

Zanzibar.

A communication was read, dated May 15th, 1925, from the Colonial Office, transmitting a copy of the Medical Practitioners Decree, 1925, of Zanzibar, which was a decree to compel medical practitioners to notify deaths in certain cases.

Methylated Spirits.

A communication was read from the Customs House, of April 9th, 1925, enclosing draft regulations, and stating that to meet objections which have been raised to the inclusion of pyridine in mineralised methylated spirits it was proposed as an experimental measure to allow the sale of industrial methylated spirits—i.e., unpyridinised—for medical and surgical purposes other than internal use by registered chemists and druggists under certain conditions. It was resolved to refer the matter to the Pharmacopœia Committee.

Transfer from Colonial List to English List.

The Committee considered an application from Alfred Spitteler, who was registered in the Colonial List on Nov. 14th, 1899, in virtue of the degrees of M.D., C.M. 1897, U. Madras. He desired to have his entry transferred to the English List, as he had since obtained the qualifications of M.R.C.S. Eng. 1905, L.R.C.P. Lond. 1905, and D.P.H. Lond. 1900. It was resolved :—

> That the name could be registered in the British List in virtue of the British qualifications on payment of the usual fees for the registration of additional qualifications, and could appear in both lists, with a cross-reference ; but that the name could not be transferred from the Colonial to the British list.

Cancellations.

A communication was read from the Royal Faculty of Physicians and Surgeons of Glasgow stating that the diploma of Mr. Haydn Brown had been recalled and cancelled during the pleasure of the Faculty. (This practitioner still possessed the L.R.C.P. Edin., 1892, and the L.R.C.S. Edin., 1892.)

Communications from the Royal Faculty of Physicians and Surgeons of Glasgow were read stating that the diploma of Mr. D. W. Anderson had been recalled and cancelled during the pleasure of the Faculty, and from the Royal College of Physicians of Edinburgh, stating that the diploma of Mr. Anderson had been suspended sine die.

Examination Committee.

This report was received and its recommendations adopted on the motion of Sir Norman Walker (chairman of the Committee) on May 29th. In the discussion following the motion, Sir Leslie Mackenzie commented on the fact that there was no examination on infectious diseases and said that the definition of infectious diseases was widening every day. Prof. Littlejohn said that in some of the examining bodies forensic medicine was not included in the final examination. He said he would raise this matter again at the next session on another report.

Education Committee.

This report was received and entered on the minutes on the motion of Dr. J. Y. Mackay (chairman of the Committee). It dealt with questions concerning the acceptance of the senior leaving certificates of the Ministry of Education of Northern Ireland, leaving certificates of the Intermediate Education Board of the Irish Free State, and the certificate of preliminary education given by the Provincial Medical Board of Nova Scotia. It was resolved to accept these certificates with certain provisos.

Public Health Committee.

This report was presented on Friday, May 29th, by Sir John Moore, chairman of the Committee. The first part of the report related to annual returns and interpretation of rules with regard to diplomas in public health during the year 1924 : 465 candidates were examined for the First Examination, of whom 319, or 68·6 per cent., passed, and 146, or 31·4 per cent., were rejected. For the Second and Final Examination, 406 candidates presented themselves, of whom 312, or 76·85 passed, and 94, or 23·15 per cent., failed. During the year the University of Liverpool gave exemption to four persons, but none of them called for special comment. No other body granted exemption during the year.

Communications from the University of Liverpool suggested (*a*) that a sanitary staff officer of the R.A.M.C. might be allowed to give the certificate in public health administration required by Rule 3 (1) (*f*) of the old rules so far as venereal diseases, inspection and control of food, and inspection of premises were concerned, and that a medical officer of health might be given discretionary powers to accept such certificates from army candidates ; and (*b*) that the responsibility of accepting a certificate of a duly qualified M.O.H. in the Dominions (or a sanitary staff officer in the Army) might rest with the University. It was resolved :—

> That the Committee were unable to entertain these proposals, or to grant the suggested concessions ; and that the University be referred to the Council's letter of Jan. 9th, 1925.

A communication has been received from the University of Toronto asking what steps must be taken in order to have the D.P.H. of that University recognised. The University were informed that the recognition could not be granted under the provisions of Section 21 of the Medical Act, 1886.

A communication, dated April 6th, 1925, was received from the University of Lucknow forwarding a copy of the following resolution passed at the meeting of the Academic Council of the University on Sept. 24th, 1924 :—

> That the General Medical Council be approached to recommend to the examining bodies in Great Britain and Ireland that the latter be moved to grant exemption to those candidates who have successfully completed training at the Lucknow University in one or more subjects (excepting English sanitary law) for the Diploma in Public Health so as to enable them to appear for the D.P.H. of those bodies without undergoing a further course of instruction in those subjects.

It was resolved :—

> That the Council cannot delegate to any licensing body in Great Britain and Ireland the power of granting such general exemptions as are asked for in the resolution of the Academic Council of the Lucknow University, dated Sept. 24th, 1924.

Applications in exceptional cases for concessions with regard to study for the Diploma in Public Health which had been submitted by the English Conjoint Board were considered and decisions were given in accordance with the rules.

Pharmacopœia Committee.

This report, on the motion of Sir Nestor Tirard, was received and approved on May 29th. The number of copies of the British Pharmacopœia, 1914, sold by the publishers between Nov. 24th, 1924, and May 22nd, 1925, was 940 copies. The number sold in the year ending May 22nd, 1925, was 2155 copies. This number was slightly lower than that for the preceding year. The total number sold since the date of publication was 49,007. A new issue of 5000 copies has been prepared. No typographical corrections were found to be required. The Government has appointed four delegates to the international conference on the unification of pharmacopœial formulæ to be held in Brussels next September, and had asked Sir Nestor Tirard, as representing the Committee, to act as chairman of the British delegation. The Committee resolved that the time had arrived for taking preliminary steps towards a revision of the British Pharmacopœia, 1914, and had given instructions for the usual inquiries to be addressed to the several governmental and medical authorities concerned, and to other bodies interested. The preparation of a new edition would necessarily occupy several years and would entail a large amount of work, to assist in which Dr. Philip Hamill, lecturer on pharmacology and therapeutics at St. Bartholomew's Hospital Medical School, had been appointed as secretary.

Dental Education and Examination Committee.

The report on the inspection of the qualifying examinations in dentistry and dental surgery held during the years 1923 and 1924 was received and adopted on the motion of Sir James Hodsdon, chairman of the Committee. The last cycle of inspections of the examinations for degrees or diplomas qualifying for registration in the Dentists Register took place in 1911. At the May session, 1923, Mr. J. Howard Mummery was appointed inspector, and the first inspection took place in June, 1923, the last in December, 1924. The inspector reported upon all the Final Examinations for a degree or licence in dentistry or dental surgery, with the exceptions of the University of London and the University College, Cork (National University of Ireland), and Mr. Mummery was thanked by the Council for his valuable reports and suggestions. The recommendations ending the report of the Committee having been moved, were considered in committee by the whole Council, and were adopted in amended form.

Finance Committee.

The report of the Finance Committee for the year 1924, presented by Sir Holburt J. Waring, Chairman of the Committee, was eminently satisfactory, the assets of the General and Branch Councils having increased by practically £8000. About £7000 of this is shown to be a surplus, and while the total income is higher by £1850, the total expenses have only been higher by £844. A wise warning closes the report, to the effect that the considerable savings which have been effected for some time past will enable the Council to meet deficiencies should they occur in the course of the next few years. The number of students entering for the final examination during this year will again be high, but the highest level of receipts has probably been passed.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 23RD, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 136; scarlet fever, 1629; diphtheria, 752; enteric fever, 37; pneumonia, 1060; puerperal fever, 43; cerebro-spinal fever, 11; acute poliomyelitis, 4; encephalitis lethargica, 91; dysentery, 2; ophthalmia neonatorum, 114. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 21 from the number for the preceding week.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 105 from measles, 16 from scarlet fever, 87 from whooping-cough, 22 from diphtheria, and 62 from influenza, as compared with 58, 68, 100, and 139 in the four preceding weeks. In London itself the deaths from influenza numbered 10, from whooping-cough 26, and from diphtheria 6.

SMALL-POX IN HERTFORDSHIRE.

A CASE of small-pox has been notified from the district of Radlett, Hertfordshire. The patient is the Vicar of Radlett, who returned from Switzerland on May 14th. Dr. Hyslop Thomson, county medical officer of health, gives us the following information: The rash appeared on May 28th. The patient had been twice vaccinated successfully, the last time in 1910. He was again vaccinated in 1919 but ineffectively. The type of small-pox appears to be the Eastern type modified to some extent by vaccination; the patient had a severe illness with an initial temperature of 103°, but is now improving The precautionary measures taken have consisted in closing the schools, vaccinating and supervising all direct contacts, and carrying out disinfectant measures in the district. No further case has been notified up to date.

Reports and Analytical Records.

INFANTILE DIETETIC MEALS: (1) MEAD'S RECOLAC; (2) MEAD'S CERTIFIED COD-LIVER OIL.

(MEAD, JOHNSON AND CO., 40–42, LEXINGTON-STREET, W. 1.

WE have received from this firm the two following preparations: (1) Mead's Recolac, a humanised milk powder, reconstructed to resemble human milk as nearly as possible in physical and chemical properties, and (2) Mead's certified cod-liver oil. (1) Mead's Recolac is a desiccated reconstructed milk requiring the appropriate proportion of water to make a fluid approximating to the composition of the average mother's milk. The butter-fat in the milk is replaced by a mixture of vegetable and animal fats, cod-liver oil entering into the mixture, and the sugar adaptation consisting of lactose with the addition of dextrose and maltose; only a part of the casein is returned in the form of potassium caseinate, derived from the whey of fresh cows' milk, as obtained from properly inspected dairies. Full instructions how to prepare the foods are issued with the preparation, which is put up in a handy tin. (2) This is a standardised cod-liver oil for use in the indicated cases, rickets being the condition definitely aimed at. We are informed that the oil is biologically tested, the requirement here being that ¼ per cent. of the oil added to a definitely rickets-producing diet will cure experimental rickets in rats in five days. The oil is put up neatly in brown bottles as a protection against possible deterioration through light.

JECOMALT.

(A. WANDER, LIMITED, 184 QUEEN'S GATE, S.W. 7.)

This is yet another method for the administration of cod-liver oil and malt extract, and we are informed that the oil present is Norwegian and of the finest quality obtainable, while the malt extract made by this firm has long been recognised as being produced with thorough care. The indications for jecomalt are those which would be expected from its make-up, while its palatability should be a recommendation where infants or invalids are concerned. In this connexion the guarantee of the manufacturers that 30 per cent. of cod-liver oil is incorporated is interesting, as there is complete absence of the characteristic odour and taste.

BELLAFOLINE.

(THE SANDOZ CHEMICAL COMPANY, LTD., CANAL-ROAD, BRADFORD.)

This is an extract from the leaves of belladonna which it is believed represents the total active alkaloids in purity and constant proportion, the superiority over atropine being suggested by the fact that only the equivalent of one-half to two-thirds of the usual dose of atropine need be given in order to obtain the desired effect. Bellafoline "Sandoz" is supplied in bottles of 20 tablets, each containing 0·00025 g., in bottles containing 10 c.cm. of the strength of 1 to 2000, and in cases of six ampoules, each containing 0·0005 g. The recommended dosage is one to two tablets, or 20 to 30 drops, three times a day, while hypodermically from one-half to two ampoules can be administered.

THE LANCET.

LONDON: SATURDAY, JUNE 6, 1925.

THE INTER-STATE ASSEMBLY.

THE Inter-State Post-Graduate Assembly of America, directed by the Tri-State District Medical Association of that country, have held their annual Congress in London this week under the presidency of Dr. CHARLES MAYO, and from the report we are able to give in other columns it will be gathered that the occasion has been thoroughly successful. The doctors from the States and from the Dominion of Canada have been offered in London full opportunities for a great post-graduate gathering; our Crown and Government, our medical organisations and institutions, with their authorities and staffs have coöperated to welcome the visitors from scientific and social aspects alike. The gathering is one of real scientific importance, as a definite movement of coöperation between the English-speaking peoples for the furtherance of medical progress. The movement, thus described by Dr. CHARLES MAYO at the inaugural session of the Assembly, cannot have any restriction implied by the use of a language; it is the glory of medicine that it knows no national confines, and what America, this country, and our dependencies do to advance medical learning will benefit all nations and stimulate all to add to the common wisdom.

PENALISING PROFESSIONAL EFFICIENCY.

IN a test case recently decided by Mr. Justice ROWLATT, the High Court has held that for income-tax purposes a county medical officer of health is not entitled to deduct the amount of his subscriptions to medical societies. The particular medical officer subscribed to the Royal Society of Medicine, the Society of Medical Officers of Health, the Royal Institute of Public Health, and the Association of County Medical Officers of Health. It is certainly a liberal list, but the Inland Revenue Authorities will not let him deduct any of the four subscriptions. They do not say the list is too long; they merely say that as a county medical officer he is not obliged to be a member of any of these bodies in order to earn his salary or hold his office. On the other side it was urged that, if a medical officer subscribes to institutions of this kind, he spends the money "wholly, exclusively, and necessarily" in the course of discharging his duties efficiently. Towards this apparently unanswerable contention the High Court was unsympathetic. Subscriptions to professional societies, the cost of buying professional literature, and any other expenses which keep a man fit for the work he is doing, cannot be deducted. If this concession were allowed, said the learned judge, anybody belonging to any profession would deduct all that sort of expenditure, and there would be no end to it.

If this is the law, we think it time it was changed. There is a matter of principle at stake. The State ought to give no kind of encouragement to the idea that, once a man has obtained a post as health officer, he can go to sleep professionally for the rest of his life. Medical science does not stand still. A medical officer who shuts his eyes to fresh discoveries or to the records of experience in other areas is like a lawyer who ignores current law reports and takes no notice of new Acts of Parliament. To keep abreast of the advances in sanitary science is a task which needs all the stimulus and assistance which medical societies can give. To perform this task is the first duty of a health officer. It should be the law that a professional man, in calculating his taxable income, may deduct whatever charges are reasonably necessary to maintain professional efficiency. The words "reasonably necessary" may be a little indefinite, but Parliament has not been afraid to use them in recent legislation. In practice an allowance of, let us say, £10 might well be permitted (subject to production of receipts if required) for cost of membership of professional societies and purchase of professional literature. In the case under discussion the sum at stake between the Inland Revenue and its victim was a matter of a few shillings only. The ingenuity of counsel for the Inland Revenue might, we suggest, be better employed in examining and checking serious cases of tax evasion in other walks of life rather than in penalising the efficiency of professional classes on whom the income-tax already presses hardly enough.

ULTRA-VIOLET IRRADIATION.

THE use of the ultra-violet end of the spectrum in the treatment of disease has arrived with rather disconcerting rapidity. The Royal Institute of Public Health devoted to the subject nearly the whole of one of its discussions at Brighton during the last week-end, and Dr. J. SAIDMAN'S monograph,[1] which has just appeared, is based on an analysis of 600 published articles as well as on 12,000 applications of his own. The medical profession generally regards with just suspicion any therapeutic agent which is claimed to have a beneficial effect on a large number of varied conditions. An exception may have to be made in the case of ultra-violet irradiation. Its use in the cure and prevention of rickets, first described by HULDSCHINSKY in 1919, has now passed from the realm of medical novelty to that of orthodox treatment. The same might be said of its use in surgical tuberculosis. Apart from these two outstanding examples, there are numerous conditions, seemingly unrelated, which are being at present tentatively treated by light therapy with encouraging results. But the ramifications of this new science, for such it virtually is, reach far beyond the sphere of practical medicine. One or two examples from the recent literature may serve to illustrate this. In a paper on Irradiated Foods and Irradiated Organic Compounds,[2] STEENBOCK and DANIELS briefly review the salient points in the relationship between the action of cod-liver oil and of ultra-violet light, and discuss the evidence which led STEENBOCK and his collaborators to irradiate the food in place of the subject. The position at present is that by irradiating such foods as wheat, rolled oats, meat, milk, and egg yolk they claim to be able to confer on them anti-rachitic properties. The compounds capable of activation are probably cholesterol in animal tissue and the phytosterols in plants. These researches lead very close to the core of the whole vitamin problem, and from the practical point of view they suggest new possibilities in therapeutics. In another sphere, that of agriculture, a paper by Dr. J. M. HENDERSON, from the Rowett Institute, Aberdeen,[3] opens up yet wider possibilities as to the part artificial ultra-violet light may yet play. In this work a very definite quantitative estimate of the effect of irradiation on calcium and phosphorus retention was obtained by balance experiments on growing pigs. The pig is notoriously susceptible to rickets and the demand of this quickly-growing animal for those elements is very great. The effect of irradiation is correspondingly marked. In some cases where rations badly balanced as regards the mineral content were being given a daily retention of 0·5 g. CaO was raised to 2·5 g. In view of these findings it would seem that the byre lit by rows of carbon arc lamps in winter, or even the irradiated pig-stye is no mere fanciful picture. The question suggests itself as to the relative importance of irradiation of the subject on the one hand and of the food on the other. While no doubt a great practical future lies with food irradiation it seems improbable that this method can call out all the many reactions which are known to result from direct irradiation of the organism.

THE SLEEPING SICKNESS COMMISSION.

The interest shown by the Health Organisation of the League of Nations in tropical disease is a very welcome and opportune development of the League's work. Many primitive countries still offer a fruitful field for investigation, and nowhere is this better exemplified than in Central Africa. An international investigation upon the great scourge which hangs like a thunder cloud over many of the most fertile regions of the earth will be welcomed by all who have the welfare of the Dark Continent at heart. Whole-hearted international coöperation is essential to control the spread of trypanosomiasis; without it the most energetic and drastic measures applied by individual governments must fail. Central Africa is controlled by six European powers, and the time has now come when a combined effort is necessary in order to rid the whole region of the one scourge which is retarding its commercial and intellectual development. Measures designed to limit the spread of trypanosomiasis, or, if possible, to exterminate it, must necessarily be based upon a complete knowledge of the many factors upon which the spread of the disease depends; it is most necessary that existing gaps in our knowledge should be filled as far as is possible. The conference which recently assembled in London under the chairmanship of Mr. W. G. Ormsby-Gore, as reported in our last issue, was composed of experts of world-wide reputations. Dr. Andrew Balfour and Dr. A. G. Bagshawe, the British representatives on the Expert Committee of the League, are to be congratulated upon the comprehensive character of the proposals which were put forward for the consideration of the conference, and which were to a great extent ultimately adopted.

The selection of the new Commission to carry out the Expert Committee's recommendations will afford satisfaction to all workers in tropical medicine. Dr. Lyndhurst Duke, who will direct the labours of the Commission, has been known for many years as an indefatigable worker on trypanosomiasis. Dr. Kleine, who has spent many years in East Africa, is a most devoted student, who first worked out the developmental cycle of *Trypanosoma gambiense* in the tsetse-fly, and by courageously inoculating himself with animal blood containing trypanosomes was able to prove the non-pathogenicity of *T. brucei* for man. The Commission is fortunate to have the coöperation of Mr. C. F. M. Swynnerton who, as an authority on zoology, especially the big game of Africa, has made the study of tsetse prevention his own. The appointments of a biochemist and entomologist are necessary in order to make such a comprehensive inquiry complete. It is a matter of considerable satisfaction that this International Commission will work on British territory and will enjoy the facilities provided by Dr. Duke's laboratory at Entebbe. The exact rôle played by the big game in the spread of trypanosomiasis to man offers many points of primary importance which should soon be settled. The whole of this difficult problem is at present in an unsatisfactory state, and so is the part played by the commoner domestic animals. Zoologists, veterinarians, and sanitarians are equally concerned in its solution. Another important point is the exact relationship between the three important pathogenic trypanosomes—*T. gambiense*, *T. rhodesiense*, and *T. brucei*—and the explanation of the degrees of virulence displayed by these organisms in different areas. Especially attention will doubtless be paid to the most practical methods of exterminating the tsetse-fly. Whether entire extermination is feasible is open to question, but much can be accomplished in greatly reducing the numbers of the fly in populated areas, as Mr. Swynnerton has shown.

Much more accurate and carefully controlled work is necessary in order to determine the value of the more recent trypanosomicidal drugs—we may mention especially "Bayer 205" and tryparsamide. Are these drugs more efficacious when given singly or, as some think, is their action more rapid and effective when non-metallic and metallic substances are combined? The combination of antimony tartrate with "Bayer 205" is another possibility which has already suggested itself to workers on these lines. The prophylactic value of trypanosomicidal drugs both in men and in animals requires reinvestigation, for it is obvious that, were any protection against infection made possible, the limitation of the spread of trypanosomiasis in Central Africa would be rendered comparatively simple. The labours of the Commission will be watched over with very great interest by the governments concerned, and its members will have the sympathy of the whole medical profession in their work.

◆

A CENTRAL PHARMACEUTICAL LABORATORY.

In the course of his presidential address at the annual meeting of the Pharmaceutical Society of Great Britain on May 20th, Mr. F. Pilkington Sargeant stated the decision of the Council to establish a laboratory for the standardisation of the substances which are the subject of the provisions of the Therapeutic Substances Bill. The standardisation of such substances as serums, vaccines, glandular preparations, organic arsenic preparations, cannot, of course, be undertaken by chemical means, and there is a field of work here which at present does not belong either to the province of the doctor, the pure chemist, or the pharmacist, although Mr. Sargeant claimed it for the pharmacist. There is at present no institution where the average pharmacist can receive training in the preparation of such substances. The lines on which the laboratory should be established are to be in the hands of an advisory committee on which the General Medical Council has appointed Sir Nestor Tirard as its representative, the Medical Research Council Dr. H. H. Dale, and the British Medical Association Sir Humphry Rolleston. The value of such a laboratory is apparent. While the medical profession will find it chiefly to reside in the examination and standardisation of therapeutic substances, the pharmacist will value most the possibilities afforded for training and research work. Some such step has long been felt to be essential if the pharmacist is to keep pace with the ever-progressing march of medical science.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

THE list of medical men included in the Birthday Honours issued on June 3rd is headed by Sir John Bland-Sutton, President of the Royal College of Surgeons of England, who has been created a baronet. Sir John Bland-Sutton is so well known as a wise professional leader, a scientific pioneer, and an open-handed benefactor of medicine, that all his colleagues will recognise the rightness of the honour awarded to him. Three medical men have been given civil knighthoods, Mr. James Berry, Dr. Harry E. Dixey, and Dr. John Robertson. The honour to Sir James Berry will give particular pleasure to a wide group of friends, colleagues, and pupils, and also to the far wider circle who are aware of the energy and devotion which he displayed during the war with the Red Cross Unit in Serbia. Sir John Robertson, the medical officer of health for Birmingham, is the well-known professor of public health in the University and a leading authority on such far-reaching questions as housing and milk-supply. Sir Harry Dixey is the chairman of the West Worcestershire Unionist Association and has done much public and political work deserving of reward.

Other honours are to be recorded along various lines of service. Major-General S. G. Moores, late R.A.M.C., becomes a K.C.B., and Surgeon Rear-Admiral Alexander Maclean receives the C.B. Dr. James Crawford Maxwell, colonial secretary of the Gold Coast Colony, becomes K.B.E., while the C.B.E. has been awarded to Dr. E. L. De Chazal, superintendent, Victoria Hospital, Mauritius, and Dr. V. R. Ratten, superintendent, Hobart Hospital, Tasmania. Dr. A. A. Morrison, British delegate on the International Maritime, Sanitary and Quarantine Board of Egypt, has been appointed C.M.G., and the Military O.B.E. has been received by Surgeon-Commander J. S. Dudding, R.N., and Major John Scott, D.S.O., I.M.S. In the Civil Division of the Order of the British Empire Dr. D. M. Cassidy, the medical superintendent of the Lancaster Mental Hospital, Dr. G. P. Bate, who has rendered service to the Home Office under the Factory Acts, and Major A. J. H. Russell, I.M.S., director of public health in Madras, receive the C.B.E. Lieut.-Colonel R. P. Wilson and Lieut.-Colonel C. A. F. Hingston, both of the Indian Medical Service, receive the C.I.E.; the former is officiating Surgeon-General to the Government of Bengal, and the latter is superintendent of the Government Hospital for Women and Children at Madras. The following received the Kaisar-i-Hind Medal of the first class: Dr. Esther G. Bare, of the Clara Swain Methodist Episcopal Mission Hospital at Bareilly, and Dr. Edith L. Young, in charge of the Palwal Mission Dispensary, Gurgaon District, Punjab.

To all of these we tender congratulations on the State recognition of their good work.

OPTICAL TREATMENT OF CONVERGENT SQUINT.

IN a paper read at the last meeting of the Oxford Ophthalmological Congress,[1] Dr. Ernest Thomson submits that there are three distinct categories of people who still require education in the importance of this subject—namely, the parent, the family doctor, and the school-teacher. What is wrong with the family doctor, he asks, who so often minimises the necessity for attending to a squint, tells the parent it will come right in time, and so on? If it is true that such family doctors are many, the answer is that what is wrong is a defect in what ought to be an essential part of their medical training. So far as the deformity is concerned, a squint in a young child will tend to cure itself in the majority of cases with time, but only too probably at the expense of the loss of useful vision in the squinting eye. Perhaps there has been an excuse for the family doctor in the past—namely, that there has been a school of ophthalmologists who have doubted the existence of the condition known as "amblyopia ex anopsia." It is perfectly true that there are cases where a squinting eye has defective vision, not because it squints but for some antecedent cause, such as corneal nebula. In such a case the squint may be more a consequence than a cause of the amblyopia. On the other hand, in cases of recent monocular squint associated with ametropia, it is the general experience of all engaged in eye work that the enforced use of the squinting eye after appropriate optical correction, if undertaken at a sufficiently early age, does prevent it from becoming amblyopic. Dr. Thomson supports this by a reference to the observations of Prof. Arthur Thomson on cave fishes and cave salamanders. The young stages of these cave animals, it seems, sometimes have eyes showing much less retrogression than in the adults. In the case of the human eye it is not suggested that there is any change in structure resulting from disuse. What Dr. Ernest Thomson suggests is that true amblyopia ex anopsia may result from the persistence of blurred vision caused by uncorrected ametropia. The latter tends to pass into the former after a certain lapse of time through true loss of function of the cerebral centres. This implies the necessity of providing young children with spectacles not only as soon as they have developed a squint—this is generally acknowledged—but even before, in cases where there are such considerable degrees of hypermetropia or astigmatism as would render the vision of the child's eyes—one or both of them—blurred.

FATTY ACIDS AND CANCER.

THAT the cells of the lymphocytic order are concerned in resisting the spread of cancerous growths has long been recognised. The accumulation of these cells in the tissues around the invading edge of a malignant growth is so characteristic that it is one of the features usually noted by the pathologist in weighing the evidence for and against malignancy. Up to the present few efforts have been made to modify the spread of cancerous processes by the stimulation of a lymphocytic reaction in the tissues, partly no doubt because until comparatively recently no agent certainly capable of producing such a reaction has been identified. In 1919, Bergel[1] demonstrated that the parenteral injection of certain fatty oils produced such a reaction, and lately Nakahara,[2] working at the Rockefeller Institute, has used this fact as the starting point of an experimental investigation into the effect of the injection of fatty acids upon the growth of implanted cancerous tumours in mice. This observer found that by the use of olive-oil injections he was able to produce a general stimulation of the lymphoid tissues; in his investigations into the inhibition of cancerous growth, however, not the oil but oleic acid and solium oleate were used. By the injection of small amounts of either of these substances it was found possible to produce profound modifications in the behaviour of implanted tumours. When implantation of the tumours was preceded by the injections the proportion of grafts which took was, in the case of the oleate, 50 per cent. and, in the case of the acid, 40 per cent., as against 90 per cent. and 80 per cent. respectively in the case of untreated controls. Where the injections were made after the implantation of the cancerous growths it was found that subsequent injection either of oleate or acid made little difference to the actual proportion of "takes." Even in this instance, however, the course of growth of the implanted tumours was considerably modified. They increased less rapidly in size than in the controls, and in section after removal the tissues surrounding them were found to show an intense lymphocytic reaction. Experiments with sodium palmitate and stearate showed that both these soaps were practically without effect either in producing a lymphocytic reaction or modifying the course of implantations. Linoleic and linolenic acids were, however, found to be almost as active in both these respects as oleic. Whether, as the above findings suggest, the activity of the fatty acids in promoting a lymphocytic reaction is a function of their degree of desaturation remains to be proved. The author, however, points out that cod-liver oil, which has a very high iodine value, is quite impotent in this respect.

[1] Bergel, S.: Berl. Klin. Woch., 1919, lvi., 915.

[2] Nakahara, Waro: Studies from Rockefeller Institute for Medical Research, Reprints lii., 1925, 95.

The therapeutic implications of these observations are obvious. The recent observation of Murray[3] that experimental secondary implants of a tumour will not grow in the presence of a primary is correlated on the clinical side by the fact that removal of a primary growth is only too often followed by the appearance of a crop of secondaries. It is almost a platitude among general practitioners that patients who bear with their cancerous breasts live longer than those who have them removed, though the last state of such patients is such as to render the extra few months of life a doubtful boon. Taking into consideration both experimental and clinical findings, it would seem probable that the seeds of the secondaries are sown long before the removal of the primary tumour. Such removal, however, withdraws the inhibition upon their development. Some agent capable of stifling the seeds before they had a chance to develop would probably greatly improve the after-results of surgical interference in cancerous eventions. The experimental observations recorded above are correlated on the clinical side by the work of Shaw-Mackenzie,[4] who long ago recommended the use of sodium oleate in inoperable cancer cases.

THE CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS.

One result of the striking alteration in recent years of the attitude of the public towards minor forms of mental aberration is a discrepancy between the supply of competent medical care and adequate institutional accommodation on the one hand and the number of patients willing and anxious to submit their condition to mental hospital routine on the other. While the prejudice against the "mental hospital" proper is slowly but surely disappearing, those newly established institutions which deal solely with the mild case are always full. The waiting list of the Cassel Hospital is of such a length as to block admissions for periods of from six weeks to three months. In some cases the mental state is not materially affected by delay in treatment; in others there is some deterioration which should at all costs be avoided, while in all there is detriment to the national health and efficiency, since many of these patients might be doing useful work if their psychological difficulty were adjusted. One way of reducing the discrepancy is to ensure such accurate diagnosis that beds which are especially equipped for the functional nerve case shall not be occupied by sufferers who do not come into that category. To assist in this direction Dr. T. A. Ross, the medical director of the Cassel Hospital, in his third annual report, has analysed the cases of organic disease admitted during the year with special reference to the differential diagnosis. While the general practitioner cannot be expected to recognise the morbid symptoms of every disease he should be competent to ascertain whether the signs presented by the various organs are those of health or not, and a really reliable sifting of cases by their doctors would save much time and money in specialist institutions. In distinguishing organic disease of the nervous system Dr. Ross places reliance on the four cardinal groups: pupillary changes, disordered reflexes, the presence of trophic lesions, and bladder trouble. He proposes to deal with some similar problem of diagnosis in each subsequent report and his special experience should be of much value in this direction. Of the 144 patients considered in this report 98 belonged to the psychoneurotic group, and of these 62 are recorded as well or much improved, a figure on which the management are to be congratulated. As in previous issues, the patients are only reported on when at least one year of after-history is available, so that the present pamphlet deals with those who were discharged before December, 1923. There is also a table showing the late results in cases discharged from the hospital during the earlier years; the majority of these are continuing well. The patients are classed in broad diagnostic groups: psycho-neuroses, drug addictions, psychoses, and organic diseases, and there is a courageous discussion of those who failed to improve and the reasons for this failure. The functional nerve case is perhaps the most difficult of all those problems which confront the modern physician; with every year it seems to multiply in variety and increase in complexity. It is only by the patient accumulation of observations and statistics that the investigators can hope to see the condition adequately pigeon-holed in the near future. These observations must essentially be made in smaller institutions where every case can be weighed individually; while much excellent curative work is done in the larger mental hospitals it is not possible for the medical superintendent of several hundreds of patients, psychotic and functional, incurable and temporary, to conduct an adequate research into his minor cases. It is to the smaller specialised institutions such as the Cassel Hospital that we look for pioneer work in the exploration of this vital national problem. Dr. Ross and his assistants are well aware of the opportunity which they have and are competent to use it.

MEDICAL SERVICES AT THE WEMBLEY EXHIBITION.

When the British Empire Exhibition was first opened in 1924 we gave a full account[1] of the elaborate medical and sanitary services which had been provided, and commented on the opportunity which was there offered to the public of seeing how its health and well-being were cared for—in place where it might least expect such an adjunct to safety and convenience. The health problem, as we pointed out, was not alone that of large transitory congregations of visitors, but also concerned a very considerable permanent population in the park largely unused to Western ideas of sanitation. It may be placed to the credit of the Exhibition authorities that the medical equipment for 1924 was slightly in excess of the public's requirements—surely an unusual record for a great undertaking of this nature. This year the medical services are organised on similar lines to those of last year, modified only by the abolition of one ambulance station and three first-aid cabinets, which experience showed were superfluous.

The medical staff at the Exhibition consists of the following officers: General Sir W. W. O. Beveridge, Director of Medical Services; Colonel Douglas Lawson, senior medical officer; and Dr. C. E. Goddard, medical officer of health. We are indebted to the director and the senior medical officer for the details of the medical services this year. The ambulance and first-aid stations now in use are: (1) The main ambulance station situated behind Australia near the south-west entrance of the Exhibition. (2) A small ambulance station fitted with men's and women's first-aid rooms, situated in the north of the grounds and near the amusements park. (3) Seven first-aid cabinets scattered in suitable positions about the grounds and the palaces. (4) An ambulance station in the stadium.

The headquarters of the Order of St. John of Jerusalem and the British Red Cross Society are situated in a large hut which has been placed at their disposal by Messrs. Main and Co. near the Civic Hall and the main ambulance station. The detachments coming on duty, usually for a week, are drawn from all over the country, and the societies take turn month and month about to carry out first-aid duties. During big days the detachments doing duty are supplemented by extra V.A.D. nurses and orderlies. Each member receives a small honorarium to help to pay out-of-pocket expenses. The two societies have made themselves responsible for the supply of drugs, dressings, and appliances.

---

[3] Murray, J.: Eighth Sci. Rep. Imp. Canc. Res. Fund, 1923

[4] Shaw-Mackenzie, J.: Internat. Cong. Med., London, 1913 (Therap. Sect.).

[1] The Lancet, 1924, i., 1127.

All the ambulance stations and the first-aid cabinets are in telephonic communication with the main station, from which a motor ambulance can be obtained to remove a case to the main station where a medical officer is always on duty. The main station is fitted with a men's ward and a women's ward each containing six beds and a special ward containing one bed, also two dressing rooms and a dispensary. The permanent staff at this station comprises a senior medical officer, an assistant medical officer, two dispensers, and two trained nurses, one of whom acts as matron. This staff is supplemented by two V.A.D. nurses and two orderlies of the society doing duty for the month. The main ambulance station deals with accidents and illnesses of all kinds, and any found to require hospital treatment are transferred to Willesden General Hospital or other suitable hospitals. Some cases are transferred to nursing homes or to the patient's own home. No cases are kept overnight, but visitors with such things as gastric catarrh, overstrain, sprains, or contusions may be detained for some hours. These and other cases are frequently assisted on their way home by motor ambulance to railway or bus stations. The other ambulance stations and first-aid cabinets are all staffed by nurses and orderlies of the societies. There are two motor ambulances and a small four-seater touring car, all supplied by the societies, which are kept in a garage adjoining the main ambulance station. One ambulance is always in the Exhibition, whilst the other may be used to convey patients to their homes. Patients, if able, pay for the use of the ambulance. Others pay part or travel free according to their financial position.

Dr. Goddard is responsible for the sanitation of the Exhibition. Daily inspections of the buildings, restaurants, conveniences, grounds, and native quarters are made by three sanitary inspectors, two men and one woman, who report to the local urban authority.

THE ACTION OF EFFERVESCENT BATHS.

IT is well known that many waters, resorted to both for drinking and bathing, contain in the fresh state a variety of gases, although as a rule their therapeutic effect is not attributed to their gaseous contents. At Buxton, for example, besides other gases, the waters contain large volumes of nitrogen and carbonic acid. These gases adhere to the body of the bather, and they are freely inhaled. What is their effect? It must be confessed that the modus operandi of what may be called semi-gaseous and effervescent baths, whether natural or artificial, is still far from being understood. They have, however, certain noteworthy features. Thus in these baths, given below blood heat, not one but two thermal actions take place upon the surface of the body, due respectively to the relatively cool water and the relatively warm gases. Again, a remarkably consistent clinical experience has shown that effervescent baths at suitable temperatures affect the frequency of the pulse, the cutaneous circulation, and the arterial blood pressure, these immediate effects being followed by others more remote. Recent work at Spa and St. Moritz[1] have helped to define the indications for this form of balneotherapy. Dr. Hediger suggests that the effervescent bath, properly given in cases of myocardial weakness, acts by training the heart and gradually increasing the force of its contractions. At the same time it slows the cardiac rhythm, a result favourable to the nutrition of the myocardium. In his view it is a form of training accompanied by slowing of the pulse. All these and other observers agree that a definite sedative effect is also produced by the bath, and a reduction of peripheral resistance, by the opening up of the cutaneous circulation. According to Dr. Hediger, the results point to a specific action of carbonic acid gas upon the vasomotor nervous system.

We have received some interesting and suggestive observations from Dr. Karl Barth, who for nearly 20 years has studied the action of natural carbonic acid baths at Kislowodsk in a valley of the Caucasus, and afterwards at Nauheim. An old saying runs that the flowers at Kislowodsk are without scent, the birds without song, and the people without souls. Dr. Barth finds some truth in this tradition, and at Nauheim also, and especially notes that many persons, who feel quite well on the higher slopes, are tired and depressed near the springs. Sensitive, anæmic, and debilitated subjects, brain workers and women, are generally affected by the atmosphere near these waters. In his experience a certain number of the cardiac cases referred to both these spas derive most benefit from the air alone, which he regards as the first grade of a "carbonic acid treatment." With reference to the carbonic acid content of the atmosphere, wider differences exist than is generally supposed. The monthly weather reports showed many years ago that the proportion of this gas in the air of the London streets was sometimes three or four times as high on a working day as on a bank holiday. Lundegårdh has recently stated[2] that green plants are stimulated to increased growth by an increase of carbonic acid up to a point, but that a proportion of about 1 per cent. becomes in many cases inhibitory. Following the analysis of gases contained in waters, made by Prof. Schmidt, of Dorpat, Barth suggests that possibly a mixture of other gases, especially of nitrous oxide, in minute and continuous doses, may be concerned with the effects of these local climates and baths. In any case, he believes that the cure of cardiac cases in these localities is a combined one, and that effervescent baths alter or increase a special action of the atmosphere. In modern times gases have been used in deadly doses. May not continuous dosage with minute quantities of various gases have a therapeutic effect? From the scientific standpoint the action of effervescent baths ought, according to Dr. Barth, to be regarded as a graduated stimulation of organs or tissues, producing certain reactions. Even minute stimuli, below the threshold value, may affect the sum of the tensions in living protoplasm, and so increase the store of potential energy in the body. The stimulus of the effervescent bath especially affects the circulatory apparatus and its potential energy. Other organs and other forms of disease—e.g., tuberculosis—are adversely affected by the same stimuli.

All the authorities above quoted agree that myocardial weakness which has resisted other forms of treatment may respond favourably to effervescent baths. The first effect may be a diminished vigour, and only a heart with reserve power ought to be treated in this way. The result of treatment is usually manifested after an interval of months. The effervescent bath, according to these views, places a keyboard of stimuli at the disposal of the practitioner. Laboratory proofs will, no doubt, in time substantiate the clinical findings. In the meantime, it is to be recognised that cardio-vascular baths, like all other forms of physical treatment, should be adjusted to each individual case rather than dosed. Definite indications for such media cannot be attached to diseases or even to functional disturbance, but only to individuals and by the study of individual reactions. It is obvious that more extensive clinical research and analysis of cases submitted to treatment of this kind at the health resorts, particularly at the spa hospitals, with graphic records during and after treatment, are much to be desired. Thousands of cardiac invalids resort to spas for relief of their symptoms, often on their own initiative, or because friends have derived benefit, and no branch of spa treatment is more deserving of attentive study. It would appear that the addition of salt in the water hastens the vaso-dilator effect. The action of carbonic acid gas and of other gases in baths upon the circulatory system is still an unsolved and interesting problem. It is not yet clear whether natural and artificial effervescent baths act in the same manner.

THE HUMAN MACHINE.

DEPRESSION is to-day the ruling factor in British industry. The remedy is held to lie in lessening costs of production, to which wages contribute the most important item. Workers need wages to maintain their well-being, and, in proportion as working hours are spent under unfavourable conditions, they need more wages to enable them outside working hours to re-establish the equilibrium of health. A question arises as to whether improvement in working conditions, carried out for the personnel as a whole, would not maintain well-being more surely and more economically than leaving it to each individual worker. Moreover, maximum production is contingent upon maximum fitness; hence, whatever conduces to fitness benefits the employer no less than the worker. The whole question turns on the importance of the human factor in relation to production. Study of the human factor is the function of the Industrial Fatigue Research Board whose fifth annual report [1] has just been published. Thirty reports dealing with special investigations have already been published by the Board and definite laws governing human activity are emerging. Nevertheless, we note with regret that British industries are reported as failing to avail themselves of the new knowledge, even though it offers a sure way of mitigating trade depression and is being adopted in other countries.

The rest of the Board's activities is far cast and includes problems of wide industrial importance, such as hours of work, accident causation, design of machinery, ventilation, and speed of learning; specific problems, such as sickness in cotton-weaving, weight-lifting, telegraphists' cramp, illumination for printing, atmospheric conditions in mines, and employment of women as pottery placers; and laboratory research into the laws of muscular exercise, weight carrying, physical fitness, vocational selection, accuracy of movement, repetitive work, and muscular skill. The value of these investigations is hard to over-estimate; much is carried out by scientific and professional men as a free gift of knowledge for a national end. Throughout its work the Board interlocks with the activities of the National Institute of Industrial Psychology which concerns itself with specific problems for separate firms. Solution of such problems brings immediate financial return to the firms and cannot therefore be undertaken from public funds, even though based on fundamental principles elucidated with their help. Practical application may throw new light on the general problem. The Institute is an organisation in full working order prepared to translate for the benefit of individual employers the advances which have been made in understanding that internal combustion machine—the human body.

The report contains several interesting personal contributions from investigators. Perhaps the first, by Mr. S. Wyatt, will attract most attention. He shows by diagram how the productivity of beginners, even at the simplest processes, increases week by week, how it varies with different types of work and of worker; for the best workers the rate of output increases rapidly and attains a high level, for the worst the rate of increase is much slower and output never attains a high level. Slow starters should at an early stage be transferred to some process for which they are better fitted and be replaced by quick starters. Miss May Smith exhibits how mental states are reflected by exceptional work curves; the nervous and neurasthenic have an exceptional mental make-up and react accordingly. They have also much sick leave, headaches, and irritability. The work curve as a method of diagnosis may be of great value. The question is discussed by Mr. E. Farmer as to whether that tendency or predisposition to sustain accidents which is now accepted to exist can be detected beforehand; he optimistically concludes there is already evidence that this can be done by properly devised tests. The importance of such a line of research is clear. Dr. H. M. Vernon discusses the significance of output as a measure of efficiency; he considers it of great value and concludes that to-day there is practically no overstrain in industry. Mr. H. C. Weston puts in a plea for giving weight to personal subjective feelings, which may go far to check deductions drawn from other sources of information. An excellent and well put together article by Miss E. M. Newbold deals with the long vexed question of how to cope with industrial sickness statistics. The author presents the wellnigh insuperable obstacles in the way of collecting comparable data, and the pitfalls awaiting the enthusiastic tyro. He who takes this way has truly a rough road to ride.

REAPPEARANCE OF GERLIER'S DISEASE.

IN the *Schweizerische medizinische Wochenschrift* for May 7th Dr. Karl Rehsteiner, of Zürich, describes a small epidemic of Gerlier's disease which he observed in the autumn of 1924. As many as seven of the eight persons living in two houses showed the characteristic signs of this disease which, according to Dr. Rehsteiner, has not been noticed in Europe since 1900. Its history is of some interest. In 1887 Gerlier, of Switzerland, described a condition which he had first observed in the summers of 1885 and 1886, although he had been in practice in the locality for 20 years. He called it *vertige paralysant*, and the triad which he considered the most characteristic of the manifestations of this disease were: (1) pareses of certain muscles; (2) giddiness and disturbances of vision; and (3) pain in the nape of the neck and back. This disease has been known since 1888 in Northern Japan as *kubisagari* (hanging of the head), for in some cases the muscles of the nape of the neck are so weak that the chin rests on the chest. The levator palpebræ superioris is nearly always involved, and the resultant ptosis is so complete that the patient has to lift an eyelid with a finger in order to see. The extensors of the arms and legs may also be temporarily paralysed, and the combination of paralysis of the extensors of the legs with giddiness is apt to suggest drunkenness. During an attack the patient complains of misty vision and sometimes of diplopia. It is characteristic of the disease that an attack usually lasts only a few minutes, and it is this transitory character which distinguishes it from certain other diseases, such as myasthenia pseudoparalytica and lethargic encephalitis. The disease begins, as a rule, in the summer, the attacks becoming more frequent and severe until half a score to a score occur every day and greatly interfere with the patient's work. They cease with the beginning of colder weather, and have never been known to be fatal. Indeed, in the intervals between the attacks the patient feels perfectly well. Investigations conducted in Japan suggest that there is a certain connexion between working in a stable and the development of this disease, and it has been observed that transmission of the disease from one person to another does not occur (except in the case of mothers suckling their infants), as persons who do not live in stables, but who consort intimately with stablemen suffering from the disease, do not contract it. In 1914 a Frenchman, Couchoud, working in Japan, cultivated a small Gram-negative coccus from the cerebro-spinal fluid and milk of patients, and the subcutaneous injection of cultures of this coccus into cats caused paralyses similar to those observed in man, the attacks of paralysis ceasing after a few days, and the cats recovering completely. Now that Gerlier's disease has reappeared in Europe, and attention has been drawn to its most characteristic features, further research will doubtless be undertaken, and new light thrown on a condition which has probably often been overlooked or mistaken for hysteria—that cloak under which so many morbid conditions have been hidden in the past.

CANCER AND THE NERVOUS SYSTEM.

IN discussing recently in these columns (May 2nd) the anatomical distribution of occupational cancers, the suggestion was made that the factor of innervation might account for the predisposition of definite anatomical sites in the incidence of different types of occupational cancers. From an article by Dr. J. Thomas in the *Vie Médicale* of Feb. 13th, it appears that the relation of the nervous system to the ætiology of cancer has been the subject of a recent monograph entitled Précancer, by Prof. C. Stajano, of Montevideo. The article of Dr. Thomas from which we quote is a review of this monograph. Prof. Stajano holds that a peripheral traumatism must necessarily react through the peripheral nerve-endings on the cells of the central nervous system, and it is this latter change which is reflected peripherally and manifests itself in the traumatised tissue. Thus, according to Stajano, the epithelial dystrophy of lingual leukoplakia establishes itself as a response of a trophic nerve-centre, the functions of which have been disturbed by an irritating agent, such as a carious tooth. In that sense every lingual leukoplakia has a nervous origin, whether it is produced by a peripheral traumatism or by the effect of such a disease as syphilis on the nerve-cells. Stajano further holds that cancer affects particularly those sites or organs which are most highly innervated. He points out that cancer arises much less frequently on a duodenal ulcer than on a gastric ulcer, and relates this fact to differences in the degree of innervation. These interesting observations are in accord with the scanty data existing in the literature concerning the relation of the nervous system to cancer. In 1907 Sir Lenthal Cheatle[1] described in two cases of cutaneous cancer inflammatory changes in the posterior root ganglia corresponding to the area of affected skin. There are also on record two cases of cancer in man developing with extraordinary rapidity as a result of a local traumatism. In Bang's[2] case an epithelioma developed a fortnight after a drop of hot tar had fallen on the skin just within the nostril. In Story's case an epithelioma had developed within four months after the conjunctiva had been traumatised by a splash of crude carbolic. Both these regions are, of course, distinguished by being sensitive to nervous stimulation. As a result of his studies Prof. Stajano holds that—

> "the part played by syphilis and by tuberculosis in the origin of precancerous dystrophies consists in the fibrotic and destructive action on the nervous system which is common to them. . . . Traumatism in general, and chronic ulceration in particular, cease to be local accidents, and must be considered as far-reaching lesions passing beyond the bounds of the organs or regions and influencing their whole regional nervous system. . . . Carcinoma becomes a syndrome of a dystrophic nature closely related to a preceding state—the precancerous lesion—the ætiology and pathogenesis of which have their foundation in the study of the ætiology and pathogenesis of the original nervous disturbance."

Prof. Stajano's conclusions are interesting but highly speculative.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXV.

THE TREATMENT OF DEMENTIA PRÆCOX.

2. THE MANAGEMENT OF A CASE.

HAVING gleaned all that he can from the parents and friends, the doctor is prepared to examine the patient himself.

Early Cases.

It may happen that sensible parents or relatives bring the patient to the notice of the physician before evident mental disturbances have arisen. The patient may be found to be mildly excited with a certain degree of incoherence of thought and a general childish demeanour and reaction, or the picture may be one of emotional apathy and resistiveness with reticence. In the former case no good can be done by any attempt at psychological investigation; the treatment must be carried out on the general lines indicated below, modified to suit the requirements. Where there are depression and apathy, however, much can be done by a painstaking effort to obtain the confidence of the patient. Very often it will be found that the apathy is more apparent than real and that the reticence is deliberately adopted rather than indicative of lack of thought process. A dramatic change in the situation can be brought about in many such instances by patience, goodwill, and a real heartfelt attempt to understand the difficulties which the patient is experiencing. An acquaintance with human nature and a sympathetic understanding are worth more in dealing with such a situation than all the scientific technique of the schools. The physician must guard against showing any surprise or emotional revolt at any of the facts which may be confided to him. Very often it transpires that the girl or boy is suffering from a serious loss of self-esteem due to some unconventional behaviour. With this feeling of inferiority there goes a sense of estrangement, of being cut off from social contact, and the attitude of the relatives is often interpreted in this light. It is surprising how completely the whole outlook of the patient may change when once he or she discovers that this secret and carefully hidden difficulty can be freely and naturally discussed with the doctor. Without betraying the confidence of the patient, the physician can often effect some readjustment of the family life or of the environmental situation and so relieve the stress of circumstance. One interview may not be, and often is not, enough to clear up the matter. It may be necessary to stop any active work, even to institute a definite sick routine for a month or six weeks. According to the response to treatment manifested greater latitude may then be allowed and the patient may be sent away for a change before taking up his life again under such circumstances as are indicated. It is unwise in these acute adolescent disturbances to permit of any systematic psychological investigation; analysis in the Freudian sense has, in the experience of most psychiatrists, been productive of more harm than good and it is certainly unnecessary.

It is desirable to relieve the acuity of perceptional life by the administration of bromides, and the following prescription may be used for a period of six months or even longer with advantage :—

℞	Ammon. Brom.	gr. x.
	Liq. Arsenic.	♏ ii.
	Sp. Ammon. Arom. ..	♏ v.
	Aq. Chlorof.	ad ℥j.

Sig. : ℥j. t.d.s., p.c.

Although there is no definite knowledge in regard to specific endocrine disturbances, yet any indication of failure or of hyperactivity of one or other of the organs of internal secretion should be noted and appropriate treatment adopted. The empirical use of compound glandular extracts is often of value; the "Elixir polyglandin," in drachm doses three times a day, may be given in this way over a period of months. Iron and strychnine should be used with care in the early stages of the treatment, but are useful adjuncts during the convalescence.

More Advanced Cases.

Where there is evident mental disturbance of a pathological nature there is no doubt of the condition, and the line of treatment to be adopted will depend upon the severity and nature of the disturbance of conduct and upon the circumstances of the relatives. The age of the patient has also a bearing on the case, because much can be done to manage the younger patient at home, whereas, for the safety of everyone concerned, the older boy or girl may have to be placed under certificate and treated in an institution. If it is decided to treat the patient away from home it is far wiser to place him in a recognised mental institution. The ordinary general nursing home does not provide the right atmosphere and much valuable time may be lost before the case is brought under the care of those who have a proper understanding of the condition. The practitioner must not forget that it is illegal to treat a certifiable patient in any nursing home other than one of those licensed by the Board of Control.

Home Treatment.

If the case is to be treated at home it is always advisable to insist on a specially trained nurse; the relatives are not to be relied on and the general nurse does not appreciate the points against which to guard. The difficulties generally encountered are impulsive behaviour or suicidal tendencies, excitement and noise, stupor and refusal of food. The treatment should be carried out in a well-ventilated room on the ground floor, having easy access to a garden, which preferably should not be overlooked, so that the patient can take exercise when desirable and so that his bed can be placed in the fresh air when the weather is suitable. It is wise to aim at keeping him in bed for at least a month or six weeks; the causal factor is exhaustion, and all expenditure of energy should be cut down to a minimum. Where there is marked restlessness with tendencies to destructiveness it is advisable to put a mattress on the floor and nurse the patient without a bedstead at all. Where he is inclined to tear up sheets and to strip himself, as is so frequently the case, he may be dressed in a strong and warmly-lined combination suiting of canvas or some untearable material and so protected from the effects of exposure. Where there is excitement with motor restlessness or depression with suicidal tendencies the room should be cleared of all breakable objects which might form sharp-edged instruments for self-mutilation. He should be kept on sloppy foods which do not demand the use of a knife and fork; a spoon is a far less dangerous implement in the hands of an impulsive patient. Emotional instability with marked depression is a sign of considerable gravity because of the liability to impulsive suicide. In such a case continuous observation is absolutely necessary and for this two or even three nurses may be required. The noisy case must be nursed in an isolated house or he will be a nuisance to neighbours. It is not correct treatment to restrain a patient mechanically or to keep him quiet by the use of strong sedatives.

Diet and Drugs.

The diet should be plentiful and contain an excess of fat in the form of butter and cream. Care must be taken to see that a sufficiency of fresh fruit and other vitamin-containing substances is included. Where the patient refuses food or is stuporous a competent mental nurse is of great assistance, but resort should be made to tube-feeding if there is any suspicion that the patient is not getting an adequate amount of nourishment; if matters are allowed to drag on, a point is reached when he seems incapable of digesting or assimilating and serious physical consequences may ensue. Feeds should be given three times in the day and should not fall below a diurnal minimum of four pints of milk, three eggs, three ounces of cream, four ounces of sugar, and the juice of an orange or lemon or whatever fruit may be available. The milk may be given in the form of custards or one of the prepared foods. A vegetable soup makes a good variant in the dietary. Any medicines, such as aperients, may be dissolved in the feed and so given at the same time. Careful attention should be paid to the bowels and to the state of the mouth, which may become very dirty. Sedatives may be found necessary from time to time, especially where there are insomnia and excitement. The administration of paraldehyde in doses of from two to four drachms, given every six hours or night and morning, may be continued for some time without any harm to the patient. The use of the more toxic sedatives over any prolonged period is to be deprecated. Sulphonal, in doses of from 5 to 15 gr. once or twice daily, soneryl, which may be given up to 9 gr. throughout the day, and luminal, in 4 gr. doses at night, have all been found useful. When sulphonal is being administered the appearance of dark smoky urine, due to the elimination of hæmatoporphyrin, indicates that the drug is accumulating and exercising a deleterious toxic effect.

During the patient's rest in bed, massage and hydrotherapy will materially assist in keeping up the physical condition and in maintaining a healthy tone in the skin and muscular system. Prolonged hot baths, at a few degrees above blood-heat for five or six hours at a time, are sometimes of great benefit in controlling restlessness. If the patient should develop acute phases of excitement the hypodermic administration of a combination of morphine gr. ¼ and hyoscine gr. 1/100–1/50 will be found efficacious. Objections to the use of hyoscine, based upon complaints from patients of "feeling held in a vice," &c., should not be considered too seriously; in these conditions of excitement it is a valuable and useful drug.

The treatment will take time. Whereas the course of physical illnesses is usually measured in days or at most weeks, that of the mental illness is measured in months and possibly years, though it is unusual for an acute mental disturbance to persist longer than a year and a half. The relatives must be prepared for at least six months' continuous treatment, and they must be accustomed to the idea that no sign of progress may appear for many weeks. A change of phase is often indicative of response to treatment; the excited patient may become depressed, stupor may replace motor restlessness, confusion may alternate with clear periods, but eventually the more acute phenomena subside, the hallucinosis becomes less vivid and disturbing to the patient, impulses are less frequent and more easily controlled, and he shows a tendency to occupy himself more consistently and to take a normal interest in affairs around him. Care must be taken not to let him re-enter life too quickly, and he should be kept under supervision and prevented from taking up any social responsibilities for at least two months after all definitely morbid symptoms have disappeared.

It will be seen that the treatment of the mental patient at home is not to be lightly undertaken, and unless conditions are very favourable it is usually better for him to be dealt with in an institution. The practitioner must exercise his discretion and judge each case on its merits, but no time should be lost in getting the patient under proper control when the symptoms are as gross as those described above.

Senior Assistant Physician, Bethlem Royal Hospital.

Special Articles.

THE MILK-SUPPLY AND ITS IMPROVEMENT.

BY WILLIAM G. SAVAGE, B.Sc., M.D. LOND.,
COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

II.*—INADEQUACY OF THE PRESENT LEGAL POWERS DEALING WITH MILK.

IT is of importance to determine whether the present unsatisfactory condition of the milk-supply is due to insufficient legal control, to the ineptitude of local authorities and failure to use their existing powers, or to factors uninfluenced by statutory regulations and enactments. There exist upon the statute book and in regulations made under different laws a considerable quantity of legislation.

The Present Statutory Powers.

The latest Act is the Milk and Dairies (Amendment) Act, 1922. Its most noticeable feature is that while it added materially to the control exercisable over purveyors of milk it did nothing to tighten the control over milk producers. The official reason for this singular omission was that the existing legal enactments were adequate for this purpose and it was merely a question of their enforcement. To quote the circular of the Ministry :—

> The Minister desires to take this opportunity of drawing the attention of sanitary authorities to the very wide powers which they already possess for the sanitary control of dairies and cowsheds under the existing Dairies, Cowsheds, and Milkshops Orders of 1885, 1886, and 1899, and the detailed regulations which have been made by most authorities under the first of these Orders. It seems to the Minister that by the careful and systematic exercise of existing powers, together with the additional powers conferred under the new Act, local authorities should be able to take all necessary steps for the protection of the milk-supply from contamination.

It is desirable to examine with some care the reliability of this official optimism.

The efficiency of the present powers involves two separate propositions. Is the enforcement of the powers entrusted to authorities who are likely to carry them out? If it be granted that there exists the utmost willingness to operate these powers, are the legal enactments so framed that effective control is possible?

As regards the first proposition it is recognised, by those in a position to pass judgment, that the heaviest contamination and that likely to be most detrimental is at the place of production of the milk, so for practical purposes we have to consider in the main the control over clean and pure milk *production.*

These powers are exercised by the local sanitary authorities and, since the vast bulk of milk is produced in the rural areas, almost entirely by the rural sanitary authorities. We are all aware that these powers, for the most part, are administered in a very lukewarm fashion and for three obvious reasons.

(*a*) These councils are composed almost entirely of farmers or of persons directly in business relationship to farmers and milk producers. By nature and training they find it difficult to realise that conditions which they have been accustomed to all their lives may be profoundly unsatisfactory, and it is asking a lot of human nature to expect them to be zealous in public health reforms which may intimately affect their pockets.

(*b*) The officers of the local authorities who have to carry out the milk regulations are appointed by these rural district councils, and zeal in milk reform is frequently no recommendation to advancement in position or salary. Rarely or never are there enough inspectors to make it possible for them to carry out their duties efficiently under the Milk Orders and Regulations.

In the county of Somerset there are between 4700 and 5000 milk producers and the work of inspection is in the hands of 19 inspectors, all but one of whom are the sanitary inspectors of their districts, with an average of 991,700 acres and with other duties more than sufficient to keep them fully occupied.

(*c*) The vast bulk of the milk produced in rural districts is not consumed in them, but is sent to urban areas. The clean and the dirty milk fetches the same price, and efficient control adds nothing to the health or economic position of the rural areas.

All cognizant of these facts know that these factors affect materially the degree and quality of the supervision exercised over milk production.

The second question is, assuming efficient administration, can the existing legal powers ensure clean pure milk. Practically all the essential powers of control are contained in the Dairies, Cowsheds and Milkshops Order of 1885 and the Regulations made under them, the 1899 Order, the Milk and Dairies (Amendment) Act, 1922, and a few powers in regard to milk scattered through different Public Health Acts. It is impracticable in the space available to consider these in detail and only their general effect can be discussed.

Inadequacy of Existing Powers.

As regards the conveyance, with milk as the vehicle, of specific infectious diseases such as tuberculosis, streptococcal sore throats, diphtheria, typhoid fever, &c., it is notorious that existing powers are inadequate, and this is true whether the disease is spread from an infective animal or from a human case or carrier. Almost all the sections have attached to them "safeguards" to protect the milk industry which largely nullify the scanty powers which they provide. Two examples may be given.

Section 9 of the 1905 Order makes it unlawful for persons who deal in or handle milk to take any part in the business if they suffer from a dangerous infectious disorder or have been in contact with a person so suffering. It only operates when there is definite knowledge on the part of the milk producer or trader, and does not affect the cases where the diagnosis is still in doubt. The harm is frequently done by the time the disease is labelled a "dangerous infectious disorder," and only last August in Somerset, in an outbreak of eight cases of enteric fever, the father of the original sufferer continued to milk his cows and handle the milk right up to the day he took to his bed and was found himself to be suffering from the same disease. The child was ill in his house for several weeks, but no definite diagnosis was made until after the father was ill, so there was no offence under Section 9. There are no powers requiring notification of illness to the local authority from premises where milk is handled.

There are no adequate powers as regards milk from tuberculous animals. Section 5 of the 1922 Act makes it an offence to sell milk from a cow suffering from tuberculosis of the udder, but with the safeguard that the local authority has to prove that the owner "knew or could by the exercise of ordinary care have ascertained that the cow was suffering from that disease." The diagnosis of udder tuberculosis is notoriously difficult even to the skilled veterinary surgeon, while there appears to be nothing to prevent the cow keeper selling the cow, without disclosure of the facts, to another milk producer.

The local authorities might do something by the appointment of veterinary inspectors to inspect systematically cows and cowsheds. The appointment would have to be made by the individual rural and urban authorities. It is doubtful if county councils could make appointments for this purpose. The only county council appointment of this kind, of which I am aware, is in Scotland, and in the county of Lanark, by agreement with the local authorities, a whole-time veterinary inspector was appointed in 1910 and this work has been continued since with the aid of a qualified veterinary assistant. The following figures from this county, for which I am indebted to Dr. J. H. Patterson (M.O.H.), are of considerable interest.

---

* Part I. appeared in THE LANCET of May 23rd and 30th, and Part III. will appear in a subsequent issue.

Year.	Number of cows inspected.	Numbers with udder tuberculosis.	Percentage with udder tuberculosis.
1910–11	31,003	37	0·119
1911–12	32,325	36	0·111
1912–13	31,938	36	0·112
1913–14	32,743	41	0·122
*1920	29,310	19	0·064
1921	33,786	31	0·091
1922	28,727	28	0·097
1923	28,174	30	0·106

* No inspections during the intervening war years.

While it is probable that some cases of udder tuberculosis are never seen by the inspectors, the percentage detected is only about one-tenth of the proportion (1 per cent.) which competent veterinary authorities give as the prevalence of udder tuberculosis in milking herds. This fact suggests that the systematic inspection in Lanark is responsible for a very marked decrease in the prevalence of udder tuberculosis in this county, and is a striking example of the value of systematic veterinary inspection.

As regards the production of clean milk, apart from possibilities of contamination with recognised pathogenic bacilli, the legal powers are even less satisfactory. They may be considered under equipment and under methods.

As regards equipment at the farm, while it is perfectly true that methods are far more important than equipment, and that the trained person can produce high quality milk upon premises exceedingly poorly equipped, it remains true that equipment is an important adjunct and greatly facilitates the application of sound methods. While the regulations are more comprehensive as regards equipment than when dealing with methods they are very unsatisfactory. No recent regulations have been made, and those in force show an almost perverse and wilful looseness of phraseology which makes it difficult to take legal action. There are no definite regulations as to an impervious floor in the cowshed (an essential), and the requirements as to light, ventilation, and water-supply are of the vaguest. The cowsheds have to be "sufficiently" lighted, "sufficiently" ventilated with a "sufficient" number of openings, the water-supply has to be "suitable and sufficient for all such purposes as may from time to time be reasonably necessary." The definition of that blessed word "sufficient," it has to be remembered, is in the hands of the rural district council, usually composed of, or controlled by, the milk-producing section of the community.

Defective Powers of Control of Milk Production.

When we come to methods of milk production it is rather farcical to suggest that there are adequate powers of control. The requirements for clean milk are in their essentials clean cows, clean milkers, clean sheds, clean milk vessels, and satisfactory arrangements to cool the milk. There are, for example, no powers to require (*a*) the approaches to the cowshed to be kept clean and free from manure to prevent fouling of the animals as they go to their sheds. (*b*) The udders of the cows to be washed or even wiped before milking, unless the producer sells milk by retail. (*c*) Hands to be washed (unless the producer retails the milk), or even facilities for washing the hands to be provided. (*d*) The milkers to wear overalls. (*e*) A water-supply to be provided adjacent to the cowsheds for washing the hands or for cleaning down the floor of the cowshed. (*f*) The milk to be cooled after milking.

No powers are available for collecting samples of milk at the place of production for bacteriological examination. About the only definite powers are in regard to the cleanliness of vessels, and these are couched in the typical loose phraseology such as that every milk vessel is to be thoroughly cleansed with steam or clean boiling water "as often as may be necessary."

The want of legal sanctions will be better appreciated when it is realised that the inspector may visit a cowshed at milking time and find therein manure-plastered cows with dirty udders being milked by a man in his ordinary clothes in which he has just come from muck-carting. The milker's hands may be unwashed and, if he is an advocate of wet milking, he can start his job by dipping his hands in the first few pulls of milk; he can sit on a filthy milking-stool from which he refouls his hands whenever he shifts to milk a fresh animal. He can milk in a shed filled with dust, from cows tossing about the hay they are eating, into an open pail which also receives fragments from the manure-covered flanks of the cow. The milk may be poured through a dirty strainer-cloth into a churn standing in the same dusty shed, and the filled churn may be left with the milk uncooled all night until delivered next morning. The inspector may stand by and watch all this being done, and I am unaware of any legal powers which he or his authority possess to stop a single one of these unhygienic practices. Yet we are told that "local authorities should be able to take all necessary steps for the protection of the milk-supply from contamination."

The nearest approach to powers to take action would be to seize the milk under Section 116 of the Public Health Act, 1875, as "diseased or unsound, or unwholesome, or unfit for the food of man," but one is doubtful whether this section could be used for this purpose, and I know of no instance in which it has been employed. A few prosecutions have been taken under the Sale of Food and Drugs Acts for excessive dirt in milk, but there are immense difficulties in using it for a case such as the above.

Defective Powers of Control of Distribution.

Legal powers for dealing with the milk after it leaves the producer are more efficient. The 1922 Milk Act gives extensive powers over purveyors of milk since it gives power to refuse registration or to remove from the register if conditions are unsatisfactory. There are, however, numerous lacunæ in the powers of control, and, for example, there are no powers to prevent the milk being sent by train in unlocked churns (much is so sent), transferring different lots of milk from churn to churn in the streets or a railway platform or other dusty place (frequently done), heating the milk to any temperature and selling it without disclosure that it has been heated (a regular practice), transferring from churns to bottles in the street, shipping the milk quite uncooled.

From the above brief summary it will be evident that the legal position as regards milk is profoundly unsatisfactory. As will be explained in a concluding article, the Milk and Dairies (Consolidation) Act, 1915, is on the statute-book but has never been put in force, but (unless again postponed) is due to come into operation in September, 1925. The need for this or some better Act is manifest.

As the concluding article will explain, the problem of a pure clean milk-supply can only in part be solved by more definite legal powers, but all authorities agree that administrative action and control are essential factors and must play an important part. There is so much discussion about milk and the control over it that it is possible that the medical profession as a whole has failed to realise that there has never been any legal endeavour to ensure efficient supervision over the methods of milk production. Public health workers have for years past pointed out this need, and after most careful discussion have elaborated essential requirements, but invariably influences other than those of public health have prevented the sanction of legal powers to ensure the provision of even a reasonably clean pure milk-supply.

The legal position in regard to the chemical composition of milk is also decidedly unsatisfactory. The regulations made by the Board of Agriculture in 1901 under Section 4 of the Sale of Food and Drugs Act, 1899, state that when a sample of milk contains less than 3 per cent. of milk-fat, or 8·5 per cent. of milk solids other than milk-fat, it shall be presumed, unless the contrary is proved, that the milk is not genuine, due to the abstraction of milk-fat or the addition of water. The average composition of milk is recognised to be well above these standards, but these low figures are fixed because the milk of individual cows, and even in special cases the milk from small herds, may fall below, and this avoids the possibility of injustice. Such a low standard, however, means that an enormous quantity of cream is abstracted and separately dealt with, an illegal procedure hardly detectable if the reduction does not fall below the 3 per cent. fat limit.

Difficulties arise in regard to a number of points such as the warranty clauses, but the main grounds of complaint are in regard to the interpretation of what is milk in relation to these standards. The appeal decision Hunt *v.* Richardson in 1916 was to the effect that even if the milk markedly infringed the above standards no offence was committed if the justices accepted the evidence of the defendant that the milk was as it came from the cow. A simple denial of tampering is frequently accepted as adequate for this purpose. The case of Grigg *v.* Smith in 1917 further confirmed this view, and emphasised that even if the farmer deliberately only partially milked his cows, retaining the richer strippings in the udder for his calves, the article was legally milk whatever the degree of infringement of these standards. As Mr. Justice Atkin pointed out during the appeal, a farmer was now entitled by law to give a preference to his calves over the babies of his customers. The general effect of these decisions has been to reduce to futility many milk prosecutions and to reduce materially the percentage of successful proceedings against milk-vendors for adulterating milk.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Public Health in the Irish Free State.

SEVERAL matters of interest were discussed in the Dail recently on the vote for the Department of Local Government and Public Health. Mr. T. J. O'Connell drew attention to the insanitary condition of many school buildings in the country. Some of them were, he said, death-traps for the children who had to spend their days in them. Dr. T. Hennessy stated that milk was often produced under appalling conditions. The Inspection of Dairies and Cowsheds Order was administered nominally in Ireland, but for any useful purpose it served it might as well not have been passed. Referring to the new county health administration system, Dr. Hennessy asked the Minister to state what salaries were going to be paid to medical officers. Unless the salaries offered included a decent margin for travelling expenses the work could not be discharged satisfactorily. He said, further, that the treatment of people, especially the poor, was very defective. They now had only one workhouse in a county where of old they had six. There was no proper way of treating people in these workhouses in an up-to-date manner. The dispensary houses, where poor people waited three or four hours a week, were in a very bad way—unfit for human habitation, badly lighted, and badly heated. There was also the gravest discontent amongst medical inspectors engaged in the administration of the Act. These men, who had to spend £2000 to secure diplomas and the necessary qualification, were paid the same salaries as were paid 50 years ago.

In reply, the Minister of Local Government, Mr. Burke, said that he thought that he was entitled to some credit for an improvement in the condition of those officers. In 1904 the average salary of a dispensary doctor was £109, while now it was £251—a substantial increase. They were trying to arrive at a fair scale for dispensary doctors, and, short of sealed order, they had done their utmost to get the local authorities to improve the position. In some counties the conditions of life were such that the salaries could not be so high as in the wealthier counties. The question of child welfare, he continued, was a very big one, in reality a question of raising the whole economic level of the country. Here they had an ideal to aim at rather than a reform that could be carried out fully at once. Considerable advance would be made in that work with the appointment of county medical officers when the Local Government Bill came into operation in October next. He could not state definitely what the salaries of those officers would be, but they would be considerable, £700, and perhaps more. Those officers would supervise the milk-supply, see to the sanitary condition of schools and other important matters, which could not be attended to without such officers.

In reply to a demand that vaccination should not be enforced, Mr. Burke stated that he was a believer in vaccination and vaccine treatment. In England, where there were exemptions from vaccination, there were frequent outbreaks of small-pox. Ireland was free from the disease, except for now and again a contact case at a seaport. Until the law was repealed it was obligatory on him to enforce the Vaccination Acts.

Mr. Burke's claim that the salaries of dispensary doctors have undergone a "substantial increase" hardly bears scrutiny. With the altered value of money £251 to-day can hardly be worth more than £109 twenty years ago.

Treatment of Venereal Diseases in the Free State.

A statement was issued a few days ago as to the present position of the treatment of venereal diseases in the Irish Free State. The estimate for the coming year is greater by £1000 than that for last year. The expenditure for last year was £8913, of which the State bore 75 per cent., or £6685. The amount covers, besides the maintenance of the treatment centres, the cost of bacteriological tests, carried out in the pathological laboratories at Trinity College, University College, and the College of Surgeons; and the supply of salvarsan preparations to medical practitioners. These remedies are supplied free, but only after the provision of evidence that the doctor applying for them has experience in administration of them. Formerly, diseases of this kind were little seen outside the chief cities, but evidence is now forthcoming that they are more widely spread. In recent years the numbers of patients treated under the schemes aided by the department have increased largely. Two treatment centres are established in Dublin, and the establishment of a centre in Cork is under consideration. Extension of treatment is a matter for satisfaction, for the reason that it does not indicate greater prevalence of the diseases—as to which, in the nature of things, no statistics are available—but it does indicate that a greater number of affected persons are seeking proper treatment. The treatment centres are at Dr. Steevens' Hospital and Sir Patrick Dun's Hospital. At both of these there is, besides the out-patient clinic, accommodation for intern treatment. The number of in-patients in 1923–24 was 7022, an increase of 240 over the previous year. The number was still greater last year, though the actual figures have not yet been returned. Out-patient attendances in 1923–24 numbered 25,000, but this figure includes several attendances of each patient. An inter-departmental committee on the treatment of venereal disease has recently been appointed, and is at present taking evidence on the subject.

THE CHARCOT CENTENARY.

(FROM OUR PARIS CORRESPONDENT.)

IN a series of brilliant fêtes, Paris commemorated last week the centenary of the birth of J. M. Charcot, and at the same time the twenty-fifth anniversary of the founding of the Society of Neurology was celebrated. The Academy of Medicine held a *séance solennelle*, in which numerous delegations of doctors from abroad took part. The eulogium of Charcot was strikingly delivered by one well qualified to speak of him—Dr. Pierre Marie, who was an intimate friend of the great neurologist, had been his "interne" and "chef de clinique," and who had succeeded Charcot in the professorial chair. His speech was enthusiastically received as he made his peroration "Charcot fut un médecin génial, un maître admirable, et un grand Francais." An impressive ceremony was held the same evening in the large amphitheatre at the Sorbonne, the President of the Republic being present, when Dr. Babinski spoke of Charcot's work and discoveries, in particular with regard to the conditions of ataxia, chronic rheumatism, intermittent claudication, exophthalmic goitre, cerebral hæmorrhage, aphasia, lateral sclerosis with muscular atrophy, disseminated sclerosis, hysteria, and many others. "To appreciate the value of a great man's work," he said, "let us, in imagination, delete his achievements from our present knowledge, and then try to assess the extent of the deficit. To lop off from neurology all the acquisitions we owe to Charcot would be to make it unrecognisable. How many mists of error did he not scatter! Of a truth, in the realm of neurology, not a day passes but we have recourse to some of the conceptions Charcot introduced; his work is always with us. One must bear in mind, too, the influence he had on a whole generation. Charcot was an inspiring force; in contact with him, the listless student acquired the taste for work, and the plodder became animated with the ambition to follow in the steps of the man who was familiarly known to his staff as 'le Patron.' If the French school of neurology still continues pre-eminent, this reputation is in no small measure due to the impetus which came from Charcot. By his genius and by his toil he served not only his country but all humanity, and it is for this reason that medical men from every land have come here to-day to join with us in paying tribute to the memory of the revered master."

Dr. Marinesco, of Bucarest, who had previously read to the Academy a paper entitled "A Foreign Student's Impressions of the Personality of Charcot," then spoke in the name of the foreign delegates, which was followed by an eloquent address from Sir StClair Thomson, of London, President of the Royal Society of Medicine.

Prof. Guillain, representing the Society of Neurology of Paris, recalled Charcot's famous credo, in which he insisted, in 1883, on the necessity for a perpetual alliance between clinical observation and the facts of anatomy and physiology. "The Society of Neurology, of Paris," said Prof. Guillain, "has adopted this credo in its fullest significance. Although much progress has been made since Charcot's death in methods of diagnosis and treatment, nevertheless, all this new super-structure has been built on the solid foundations laid by Charcot—or, to change the metaphor, the harvest has ripened on the field which his ceaseless toil first broke."

The meeting concluded with a noteworthy speech from M. de Monzie, the Minister of Public Instruction. In addition to these tributes, mention must be made of the series of articles on "Charcot Intime," written by Dr. A. Souques, one of his pupils, which appeared in the *Presse Médicale*. Another review of Charcot's life and work in *Figaro*, by Dr. Maurice de Fleury, who knew Charcot intimately, gives us an amusing glimpse of the great man behind the scenes. At the height of his fame Charcot was consulted by patients from Japan, India, Russia, the coasts of the Pacific, and many other distant countries, and even grand dukes had to kick their heels in his ante-chamber, what time the great neurologist attended to much more important things. He was subject to reveries and short attacks of melancholia during which it was well for even his most intimate friends not to disturb him. It has been said of him that he lacked modesty, but Dr. de Fleury modifies this judgment, pointing out that it would be more correct to say that Charcot despised the pose of modesty affected by those who are most thirsty for praise. He was apparently a good judge of contemporary genius, and he at once appreciated the greatness of Pasteur. It is curious, by the way, that the disease known in England as Charcot's disease, is spoken of in France as *arthropathies tabétiques*. This tendency of a country to relegate the honouring of its own prophets to others is also to be observed in the fact that the disease known as Barlow's disease on the continent is modestly named infantile scurvy in England.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Disappearing Rural Doctor.

THE increasing tendency to specialise in medicine with the correlated shortage of general practitioners is causing increasing concern in this country, and particularly in rural areas. Dr. G. E. Follansbee, the retiring president of the Ohio State Medical Association, recently chose this subject as the theme of his farewell address. There can never be a successful "back to the farm" movement, he says, unless we provide more doctors in the country. As it is, the modern graduate, tempted by the large fees and congenial associations of the city, rarely settles at any great distance therefrom. Dr. Follansbee would cut down the pre-medical requirements and discourage specialisation. Dr. Ray Lyman Wilbur, past president of the American Medical Association, speaking at Boston to the Association of American Medical Colleges on March 5th, held that since a physician must be world-wise to be a satisfactory guide to many of his patients, it is essential not only that he should have a first-class college education, but also that his medical curriculum should be planned to broaden his public and social conceptions. He would eliminate from the medical course "the refinements of the specialities and the intensities of the laboratories."

A very careful study of the whole problem was made last year for the General Education Board.[1] The authors give reasons for doubting whether a lowering of pre-medical standards would result in a larger supply of students. Moreover, they point out that the larger towns are already super-saturated with physicians "engaged in an incessant and vigorous competition." They find the root of the matter not in the medical curriculum, but in the social and economic disadvantages of the rural practice. "No matter how severe the competition in the medical profession may become," they say, "it will not compel a physician to live in a place where a living cannot be made." The most hopeful avenue of development, to their way of thinking, is the county-town hospital serving the needs of all the physicians in the county. This method, it will be seen, presents the possibility of some degree of specialisation to the country physician, introduces the laboratory, and calls for a raising rather than a lowering of educational standards.

---

Coöperative Medical Education.

At Loma Linda, in California, the dean of the medical school, Dr. Newton Evans, has introduced the "coöperative" plan of education. The 90 freshmen have been divided into two groups, and while the first division is at work in school the second is earning a livelihood somewhere in the neighbourhood. The groups change places every month. The employments found for students include nursing and general orderly (17), pharmacists' assistants (5), laboratory and X ray technicians, ambulance men, and assistants in physicians' offices. Dr. Evans reports that the plan is a success from every point of view. The students make more rapid progress, besides saving money. Opportunities are available for four times as many students as the number now employed.

Obituary.

JAMES SCOTT, M.B., C.M. EDIN.

THE death occurred in a nursing home in London on May 29th of Dr. James Scott, a former Governor and medical officer of H.M. Prison, Holloway. Born at Leith in November, 1853, he received his medical education at Vienna and Edinburgh, graduating M.B., C.M. Edin., with honours in 1877. After a period spent on the resident staff of hospitals at Bristol and elsewhere, he joined the prison service in 1881, entering with the highest testimonials from Lister, Clouston, Matthews Duncan, Grainger Stewart, and others. After serving at Dartmoor and Chatham convict prisons as assistant surgeon, he became successively medical officer at Manchester, Stafford, Holloway, and Brixton prisons.

A colleague, W. N. E., writes of him :—

> "Probably Dr. Scott's happiest and most valuable official work was during his tenure of office as medical officer of Holloway and later Brixton prisons. There the remand and local prisoners of the metropolis and outlying areas came under his observation, and his wide experience, extensive knowledge in forensic psychiatry, impartiality, and thoroughness, soon made him an invaluable witness in the criminal courts, a recognised authority on criminal responsibility, and earned for him the confidence of the judges before whom he appeared. Throughout his career a hard worker, he never spared himself and accepted the responsibilities of his office with courage and modesty, and when the strenuous years of court work began to tell he was offered and accepted the post of Governor of Holloway prison and continued as such until his retirement in 1912. He was an ideal colleague, unselfish, generous, and understanding, and after a long day in court would return to the prison to discuss with his juniors such points of importance as had been presented to him a few hours before in the witness box. During these years he studied much, and was well versed in continental work on crime and insanity, but he wrote little. The only paper the writer can recall is one on the Death Penalty, read before the Medico-Legal Society, of which he was one of the earliest members, and at one time vice-president. But his counsel was constantly in demand when questions of criminal responsibility wereunder consideration."

A bachelor, Dr. Scott enjoyed to the end the devoted attentions of his sister, to whom numerous friends will extend their sincerest sympathy.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirtieth meeting of the Commission was held at the Home Office, Whitehall, on May 28th, Lord Lawrence of Kingsgate in the chair. Evidence as to the possibilities of assistance to the hospitals from the Insurance Scheme was given by the British Hospitals Association, represented by Mr. H. Wade Deacon, Viscount Hambledon, and Mr. J. Courtney Buchanan; by the Middlesex Hospital, represented by Mr. A. E. Webb-Johnson and Mr. Walter Kewley; and by the Sheffield Joint Hospitals Council, by Sir Henry Hadow and Mr. S. R. Lamb. Thereafter Mr. Owen Aves, Mr. Francis Gregg, and Dr. James Forrest, representing the Institute of Ophthalmic Opticians, were examined on the nature, extent, and cost of optical and ophthalmic treatment of insured persons. Proof copies of the oral evidence and the relative statements submitted at the meeting of May 14th are now on sale at H.M. Stationery Office (*2s. 3d.*).

Correspondence.

"Audi alteram partem."

THE ENDOCRINE FACTOR IN CHRONIC ARTHRITIS.

To the Editor of THE LANCET.

SIR,—Doubtless many, like myself, perused with interest the annotation on this subject in THE LANCET of May 9th. That an endocrine element intervenes both in the rheumatoid or atrophic and the hypertrophic type of arthritis deformans cannot be gainsaid. In 1902 I drew attention to the frequency with which vasomotor phenomena—clinically indistinguishable from true Raynaud's disease—preceded and accompanied rheumatoid arthritis.[1] Also that I had seen several examples of the *coexistence* of Graves's disease —complete or larval—with rheumatoid arthritis. Moreover, having observed that, in instances in which the Graves's syndrome *preceded* the rheumatoid arthritis, *recession* of the thyroid swelling occurred before the onset of joint swellings, I suggested that in cases of rheumatoid arthritis "with apparently atrophied thyroids and possibly in others some benefit might accrue from thyroid administration." Dr. H. K. Thompson is incorrect when he states that I "found 6 out of 14 cases of rheumatism with incomplete Basedow's." As a matter of fact, in 1903 I recorded 14 examples of the complete and six of the larval or incomplete type of Graves's syndrome coexisting not with "rheumatism" but with *rheumatoid arthritis*.[2] Fourteen of the 20 cases also suffered coincidently with Raynaud's disease, and in my work on "Arthritis Deformans," I pointed out that it was precisely in cases showing these vasomotor phenomena that thyroid therapy proved so beneficial. That following thyroid exhaustion in Graves's disease a condition of rheumatoid arthritis may supervene would seem to suggest that the latter disorder develops by preference on a *hypothyroidic* substrate. Certainly one notes frequently minor signs of hypothyroidism in rheumatoid arthritis, and often simultaneously, too, symptoms suggestive of the reverse condition—*hyper*-thyroidism—tachycardia, sweating, &c. That a condition of hypothyroidism favours the onset of rheumatoid arthritis is strongly suggested by the following sequences. Thus, in a case of Graves's disease under Pauchet, rheumatoid arthritis with scleroderma developed consecutively to thyroidectomy —both conditions clearing up under thyroid therapy. Peppo Acchiote cites a woman, aged 28, with hypertrichosis of chin and neck treated by X rays. By the eighteenth séance she had developed well-marked myxœdema and widespread arthritis, which responded dramatically to thyroid therapy.[3] Deaver, too, recently remarked that after thyroidectomy the patient's resistance to "rheumatism" and "endocarditis" appears lowered. Again, a previous history of rheumatic fever is strikingly common in rheumatoid arthritis. Now, while rheumatic fever is well recognised as predisposing to Graves's disease, it is not so well realised that it is more often followed by a state of *hypothyroidism*. The sequence, (1) rheumatic fever, (2) hypothyroidism, (3) rheumatoid arthritis, is not uncommon. During the intermediary stage of hypothyroidism the subjects commonly display vasomotor phenomena or muscular cramps indistinguishable from tetany, in addition to minor signs of hypothyroidism. As to the *hypertrophic* type or osteoarthritis, which occurs so commonly in women at the menopause, I emphasised in "Arthritis Deformans" the extreme frequency with which it was associated with hypothyroidism, myxœdema, and goitre, and the value of thyroid therapy.[4]

[2] Graves's Disease in Association with Rheumatoid Arthritis, Brit. Med. Jour., 1903, i., 1015.

[3] Types of Rheumatoid Arthritis, with Suggestions as to Thyroid Treatment, Edin. Med. Jour., 1904.

To sum up, in my opinion, the "sub-thyroidic" is identical with the "arthritic" diathesis as, alike in the "rheumatism" of childhood, the rheumatic fever of older subjects and in rheumatoid arthritis and osteoarthritis, we find this same hypothyroidic taint. If my contention be true, it follows that the original predisposing factors that make for the development of these joint disorders must be sought for in those conditions—intrinsic and extrinsic—that determine the production of *hypothyroidism.* Of the determinants of hypothyroidism the most outstanding is goitre, and it is, I think, significant that the death-rate and incidence of rheumatic fever, cardiac rheumatism, rheumatoid arthritis, and osteoarthritis is markedly higher in regions traversed by the Pennine, Cotswold, and Mendip ranges, the traditional, but by no means the exclusive, sites of endemic goitre in this country.

I am, Sir, yours faithfully,
LLEWELLYN JONES LLEWELLYN.

Upper Brook-street, W., May 25th, 1925.

HEREDITY IN MENTAL AND NERVOUS DISEASE.

To the Editor of THE LANCET.

SIR,—In the leading article on this subject in THE LANCET of May 16th you state that the progress of *Homo sapiens* has been not biological but sociological; and that progress has depended on his control of and ability to grow at the expense of his environment. I feel that such an opinion is one with which nearly everyone will agree, and yet as a worker in tuberculosis I find much which cannot be explained only on a sociological basis. It is rather that sociological changes, diet, education, breeding, and whatever factors modify family life do have a much more profound biological result than we imagine.

I find in experiments in cattle that if the young female is not well cared for until she calves; if, especially, her ration in protein is not adequate, or if she suffers too much exposure, her calf is born with an inability to thrive. If a bull calf, he is of poor constitution and makes poor use of his rations. Later he is often found late in developing sexual characteristics. If such a bull is used, his calves nearly all develop tuberculosis early and acutely. I find, however, that the offspring of such a bull from heifers are usually of much poorer constitution than the offspring from cows which are manifestly tuberculous. I have thought that the older cow, even if tuberculous, could afford to deplete herself more than an immature animal could, in order to correct the fault in the male germ cell.

In experiments in immunisation of cattle, I found that using the protein from the tubercle bacillus on cows before calving that the health of the cow improved, and the subsequent calf was much more of a thriver. At the same time, although it was thus feasible to promote immunisation antenatally, I found in numerous experiments that the greatest immunising agent is a resistant sire. The female, like the soil, will respond if cared for, but the sire must be right. I considered that the best sire was an immunised sire, or one known to be strongly resistant.

That such factors hold in the human race I believe from a considerable experience of tuberculosis in this country and in Western Canada. When stock deterioration sets in, the female suffers, and then her male offspring, even if he grows up to be a fair specimen of a man, is apt to bring children into the world that nobody can do anything with. In nature such males would be wiped out quickly. Contending, then, that society aids in man's progress, it can only do so as long as it continues to perform the duty of batman to Mother Nature herself. So George Meredith thought.

If man's progress is sociological only, then we cannot stand. Nature will have nothing to do with helpers who forget her stern method of soil replenishment. For then early death becomes a biological necessity. A point of importance, too, is that a breeder on poor land may, by buying in concentrated food actually create a higher class of animal than a breeder on good land. The peril of the breeder on good land is that he relies too much on his good grass; while the peril of the breeder on poor land is that if business is bad, the stock deterioration must be faster, if it does not pay to buy in food for them.

This country resembles the latter breeder. We have moved along sociological lines and have been able to sustain a high standard of society by buying in our protein from abroad. At the present moment there is some deterioration owing to the lower standard of wages and so on. The women suffer as usual; and while all sorts of remedies may be suggested, none are of great value, excepting forbearance towards overstocking. The deterioration will be swifter in proportion to the inability to rear good in preference to many inferior stock—stock prone to be infected. Therefore the comfort that comes from attention to a betterment of the environment may be short-lived and also it may prove too costly.

The strengthening of the hereditary factors is of vast importance. This is a difficult matter; yet much could be done by a fuller realisation that biological laws are bound to be paramount in the long run.

I am, Sir, yours faithfully,
J. J. THOMSON,
Chief Clin. Tuberculosis Officer, North Riding of Yorks.

May 20th, 1925.

THE RÉGIME OF FLUIDS IN VARIOUS FORMS OF NEPHRITIS.

To the Editor of THE LANCET.

SIR,—In patients suffering from various forms of nephritis it is essential to regulate with care the fluid intake, as damaged kidneys necessarily modify diuresis, and therefore the rôle of water in the body. I here suggest some guiding points in the administration of fluids in various forms of kidney trouble.

Acute Forms of Nephritis.—Milk is the régime of choice for the acute forms of nephritis, as milk, while it is a complete form of alimentation, possesses the advantage of constituting a diet which is both practically free from sodium chloride and is diuretic. One litre of milk contains only 1·50 to 2 g. of NaCl, along with 40 to 50 g. of lactose, an essentially diuretic sugar. But milk diet, putting aside all question of digestibility, possesses one grave defect in that it is purely a fluid diet. For every 1000 g. of milk there are about 850 g. of water. That point should never be lost sight of when a patient suffering from acute nephritis is put upon a milk diet. The milk must be graduated in relation to the functional possibilities of the kidney, and should therefore be divided into small doses, which can be distributed over the whole 24 hours, the quantity of the doses being determined according to the amounts of urine which the kidneys are capable of eliminating in the 24 hours.

Chronic Forms of Nephritis.—The fluid régime differs according as one has to deal with the three great syndromes which either singly or all together characterise the evolution of these conditions: (1) The chloruræmic syndrome; (2) the syndrome of hypertension; (3) the nitrogen-retention syndrome.

(1) *The Chloruræmic Syndrome.*—Here the fluid régime must overcome the chloride retention, and milk diet is therefore indicated. But in forms of chronic nephritis this diet, if prolonged, will cause dyspeptic disturbances. Moreover, after the lapse of some days it acts neither upon the œdema nor upon the albuminuria. Milk must be reserved for acute attacks with more or less grave threatenings of uræmia. Otherwise the patient is put on a mixed diet, or even one without milk, but always dechlor-

---

[4] Arthritis Deformans, pp. 226–229, 1909.

urated, and the beverages consist of diuretic mineral water, increased in proportion as the power of elimination on the part of the kidney becomes more marked.

(2) *Syndrome of Hypertension.*—It is in the syndrome of hypertension that the régime of fluids perhaps requires the most delicate handling; but it is also in this syndrome that when it is well ordered and strictly supervised, its utility is specially manifest. It was only a short while ago that this water treatment of hypertension was first attempted. A few years ago it would have seemed to be a dangerous error to suggest the giving of fluids to patients whose greatest trouble was that of hypertension. It was known, however, that the evolution of these cases of hypertension was characterised by a tendency on the part of the organism to auto-intoxication, principally due to renal and hepatic angio-sclerosis. Physicians attached to hydro-mineral diuretic stations have shown by their detoxication treatment that the real danger did not consist in giving beverages to such patients, but in withholding the beverages from them. At one time the classic treatment was the dry diet. To-day the good effects of treatment by diuresis are recognised; fluid régime in cases of hypertension is well-defined and definitely established. But the water treatment requires caution. The treatment must be supervised with the sphygmomanometer at hand, and with the check upon elimination of urine always in view, for over-distension of the vascular system is always possible, and excess of arterial pressure may result from an attack of angio-spasm. But with these precautions good results may be obtained from diuresis treatment such as that employed at Vittel. The dosage of fluids is carefully regulated and the fluids are taken fasting, early in the morning or late at night, the patient lying down (clino-statism). The sum-total of the fluid ingested should never be great. One must always aim at adequate diuresis without polyuria, which could only be preceded by an increase in the volume of blood and increase of blood pressure, possible causes of immediate untoward events.

The patients who secrete much water during the day should be put on a relatively large amount of fluids. But those who secrete water mainly during the night (nycturia) should be very carefully watched. All excitants of the cardiac nervous system, alcohol, coffee, and tea, should be forbidden. The bouillons and meat-juice which possess vaso-constrictor properties and cause a rise in the blood pressure should also be interdicted. And it is very particularly in such cases that beverages taken late at night are specially desirable. Drinks at meals should always be restricted.

(3) *The Nitrogen-Retention Syndrome.* — In the nitrogen-retention syndrome the permeability of the kidneys is specially affected in all its modalities. Here uræmia assumes a threatening aspect. The diet should be of low nitrogen content, as often as possible lacto-vegetarian and slightly dechlorurated. As a rule there is no œdema. The water is no longer retained by the salt and is not dependent upon chloride retention. But, as a set-off, arterial hypertension and cardio-vascular phenomena are almost always present. At all costs, fatigue of the heart must be avoided. With that aim in view the amount of fluids must be reduced and they must be distributed in small doses frequently repeated in order to obtain adequate diuresis. "The Fractional Diuresis Test," which I discussed at length in The Lancet,[1] indicates what is the secretory power of the kidney for water, and gives the precise indications for the drink régime. If a kidney can only eliminate 60 c.cm. of water at the most every half-hour, or else 50 or 30 c.cm., it is 60, 50, or 30 c.cm. of water that should be given as a maximum every half-hour. Thus one is enabled to obtain the maximum diuresis without in any way overtaxing the cardio-vascular system.

I am, Sir, yours faithfully,

P. L. Violle,

Consulting Physician at Vittel; Director of the

May 25th, 1925. Laboratory, Institute of Hydrology, Paris.

CLEAN MILK IN HOSPITALS.

To the Editor of The Lancet.

Sir,—Since the autumn of 1917 the health committee of the city of Worcester has had a small herd of dairy cows, free from tuberculosis, in a farm which it has established adjoining the isolation hospital. The committee for some years previous to 1917 had endeavoured to obtain milk from the neighbouring farmers from cows certified to be free from tuberculosis, but no farmer in the neighbourhood would contract for milk on those terms. The small herd of cows is managed by a herdswoman who is well trained and competent for the work, and the results have year by year been very satisfactory.

It is an astonishing thing to me that the educated British public are so apathetic as regards their milk supply.—I am, Sir, yours faithfully,

Mabyn Read, M.D.,

May 26th, 1925. Medical Officer of Health, Worcester.

EXCESSIVE INFANT MORTALITY AT MARKET DRAYTON.

To the Editor of The Lancet.

Sir,—I note in your issue of May 16th a reprint of my question to the Minister of Health with regard to the infantile mortality of Market Drayton which is double that of the neighbouring Newport, and thrice that of Wellington, the other contiguous locality. I presume that there must be reasons for this unhappy phenomenon, which I see was noticed at a public meeting in the place itself held early in this month. As a report on the subject exists, it is curious to speculate on the reasons which have prevented it from being made public. In the interests of Market Drayton itself one would have supposed that the evil being recognised, the remedy should be prescribed.—I am, Sir, yours faithfully,

House of Commons, May 27th, 1925. C. W. C. Oman.

BAKER'S ITCH AND WORKMEN'S COMPENSATION.

To the Editor of The Lancet.

Sir,—The question raised is hardly as simple as Captain J. T. Ainslie Walker would suggest. I have had under my purview as many cases of dermatitis in confectioners as in bakers. The symptoms in both have been practically indistinguishable. No improvers are used in the confectionery trade. Again, of the number of cases of "baker's itch" which have been under my personal care, so far as I could ascertain, only about one-half were using flour which was supposed to contain improvers.

I am, Sir, yours faithfully,

Wigan, June 2nd, 1925. R. Prosser White.

THE BATEMAN APPEAL FUND.

To the Editor of The Lancet.

Sir,—In spite of the generous and chivalrous support of The Lancet, and in spite of the appeals that others of us have made—made on behalf of one of us in dire distress—only a few more pounds have been added to this fund. It is difficult to realise that such indifference can exist in our profession; a British court of justice seems no longer our standard of right and wrong. It is harder still to think what the great names of the past would think of our indifference; generosity was ever their supreme characteristic. I enclose a third small contribution in the hope that those who are too busy, those who are successful, those who are indifferent, and all those who pass by, may for a moment pause and put themselves in Dr. Bateman's position and by so doing may be stimulated to help a colleague passing through a physical and mental anguish we may all well hope to be spared.

I am, Sir, yours faithfully,

Margate, May 31st, 1925. A. Graham-Stewart.

INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.

VISIT TO LONDON, JUNE 2ND–6TH, 1925.

President—H.R.H. THE DUKE OF YORK, K.G.

INAUGURAL MEETING.

ON the morning of Tuesday, June 2nd, at Wigmore Hall, Wigmore-street, when the Duke of York presided over the inaugural ceremony, His Royal Highness, in extending a cordial welcome to the Guests from Overseas, said that some came as representatives of a great and progressive nation with which already we had so much in common, while others were our own kinsmen from Canada, a vast Dominion of self-governing peoples whose record of service to the Empire was unsurpassed. These considerations alone, he said, would have ensured for the Assembly a more than friendly reception. But further, our guests, he said, formed a great army of skilled physicians and surgeons whom we were delighted to honour, so that the members of the medical profession in this country were united in their desire to accord to the Assembly a hospitable reception, and to make the occasion both instructive and enjoyable. The names of the distinguished lecturers and demonstrators on the programme showed, he held, that the time of the visitors would be well spent, for they would secure at first hand the views and opinions of those whose knowledge and skill had combined to raise them to their highest rank in their profession. In conclusion, His Royal Highness said that it was his earnest hope that when the members of the Interstate Post-Graduate Assembly left our shores they would not only have obtained professionally some benefit from this visit, but that they would also take back with them the happiest recollections of their brief stay in our midst. Expressing his appreciation of the honour which he felt at being made an honorary member of the Assembly, the Duke of York said he had been much interested in its history, and thought that Dr. Mayo was to be congratulated on the growth and expansion of an organisation which in the short space of nine years had done so much valuable work. He congratulated Mr. Franklin on the devotion of much time and energy to the organisation of the visit, and declared the meeting of the Assembly open.

Mr. Neville Chamberlain, the Minister of Health, said that he was happy in being permitted on behalf of His Majesty's Government in general and on behalf of the Ministry of Health in particular to add to the President's words of welcome. To cross the Atlantic was no longer the adventure that it was a few years ago, but he realised that many of his hearers must have travelled hundreds of miles before setting foot on board ship, while all must have made special arrangements in order that their work might be adequately carried on during their absence. It was, therefore, a compliment of no common order to this country that they had thought it worth while to be present. Among the guests, he pointed out, were representatives of every city in the Dominion of Canada and every State in the American Union, and it was gratifying, in this small island, to be able to open arms to a whole continent at once. It was, too, an impressive thought that our visitors would carry back with them the results of their observations and the additions to their knowledge and spread them broadcast through so vast an area, returning to fight the great enemy of humanity, disease which knew no discrimination between nation and nation, reinforced and invigorated by experience of methods that had proved effective in the hands of others. The benefits, he concluded, would not be all on one side, for our physicians and surgeons would learn from contact with their guests, and he wished to all the Assembly a time of pleasurable and profitable study.

Sir Humphry Rolleston, President of the Royal College of Physicians of London, in extending the warmest welcome to the overseas colleagues, said that meetings such as these increased, if that were possible, sympathy as well as promoting common action. Medical men were students all their days and were most anxious to learn how they could best apply their studies as post-graduates and so keep up with the ever-advancing tide of medical knowledge. Post-graduate education was a very urgent problem in London and much could be learned from the American visitors. Less than ten years ago there was a Tri-State Assembly which had now extended and included all the provinces of Canada and all the States of the Union, and we, in this country, had much to learn from such an organisation. In conclusion, Sir Humphry Rolleston referred to that "beloved physician," Sir William Osler, who would have welcomed such a meeting, while he paid a special tribute to the honorary organiser of the Assembly, Mr. Philip Franklin.

Sir John Bland-Sutton, President of the Royal College of Surgeons of England, drew a humorous parallel between the migration of birds and the irruption of doctors from Canada and the United States under the leadership of Dr. Mayo. It was a good thing, he said, to meet a man face to face in his own wards or operating theatre, but better still to meet him socially, for in this way lasting friendships were formed. As President of the Royal College of Surgeons of England he bid them welcome.

Mr. Alanson B. Houghton, the American Ambassador, on behalf of his countrymen, thanked the Duke of York for his support of the Assembly. In accepting the presidency of the British organisation, he said, His Royal Highness had furnished one more evidence of the reality of those friendly ties which bound the countries and peoples together. The gathering to-day would recall the comradeship of the British and American medical professions in war, now followed by a comradeship in peace. Further, he desired to thank Mr. Neville Chamberlain for his interest and goodwill, and it was a source of distinct satisfaction that the Minister of Health should be here to welcome them, for no man was more keenly interested than Mr. Chamberlain in seeking to bring about a fuller coöperation in research. To Sir Humphry Rolleston and to Sir John Bland-Sutton they also owed a debt, and he could only hope that one day they would be able to repay it in some slight degree if both those gentlemen would honour the United States by a visit. To the honorary staffs of the numerous hospitals, who had combined to make up a full programme of post-graduate work, and to Mr. Philip Franklin he further expressed a debt. Nowhere else than in England, as he knew from experience, would his compatriots find a hospitality so generous, gracious, and altogether delightful, said the Ambassador, while warning the visitors against its potential dangers.

Dr. Charles H. Mayo expressed the great pleasure that it gave the members of the Assembly to have a Royal welcome seconded by many able and representative speakers of England. Such a welcome would be recorded in all the States and Provinces of North America; it would add to the warmth of feeling for the mother country, and would bring together more closely the English-speaking peoples and maintain their high position in all scientific work. In conclusion, and addressing the Duke of York, Dr. Mayo said the Assembly had hitherto had but one honorary member, Mr. Coolidge, the President of the United States, but now they wished to double the honorary membership and if it be His Royal Highness's pleasure, Dr. Mayo said, "by and with the authority vested in me by the members of the Interstate Post-Graduate Assembly of America I herewith and hereby declare you an honorary member of this Association with all the rights and privileges pertaining thereto."

His Royal Highness having vacated the chair, a series of brief lectures, introducing fundamental scientific questions, was commenced.

THE ÆTIOLOGY AND MEDICAL TREATMENT OF GALL-BLADDER DISEASE.

BY SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D.

A KNOWLEDGE of the causation of gall-stones and inflammation of the gall-bladder is, of course, essential for satisfactory treatment.

In the first place it should be mentioned that the clinical label of gall-stones or cholelithiasis is often and naturally used for symptoms common to them and to inflammation of the gall-bladder—conditions very often combined but also occurring independently. Although a distinction is drawn between them in systematic treatises, and of course exists, they are very closely bound up together, being often successive or alternating stages in the patient's history and giving rise to very similar symptoms. Unless a calculus is indicated by X ray examination or is passed in the stools, a diagnosis of gall-stones, even though there may have been an attack of acute biliary colic, is open to doubt, and yet it is more often made than the less committal one of cholecystitis, which in the original but now forgotten sense means merely disease of the gall-bladder. It is, of course, true that the termination *-itis* now has a universal significance of inflammation, but it was not always so. Originally the affix -itis was a Greek feminine adjectival termination, and in words like neuritis, peritonitis, pleuritis, agreed with νόσος (disease) understood, so that, for example, ἡ νευρίτις νόσος simply meant *the* disease of the nerves; the implication that *the* disease of organs was inflammatory came later. In a somewhat similar manner melæna signifies *the* black disease, and pneumonia *the* disease of the lungs.

The Formation of Gall-stones.

There are two distinct views about the formation of gall-stones :—

(1) The infective or inflammatory theory enunciated by Naunyn is to the effect that a local inflammation of the gall-bladder walls leads to an increased formation of cholesterol by the epithelium lining the gall-bladder, and that the liberated cholesterol is cemented together by bilirubin calcium. According to this view, cholecystitis is a necessary antecedent to the formation of calculi, but it has been urged that cholelithiasis does not invariably follow cholecystitis, and therefore that some additional factors, such as an increased amount of cholesterol, stagnation with excessive concentration of the bile in the gall-bladder, are necessary. It should be noted that concentration of bile to perhaps one-eleventh of its original bulk is a normal function of the healthy gall-bladder (Rous and McMaster), and that therefore an excessive concentration, such as might occur in stasis, must be premised. That infection of the gall-bladder and biliary stasis cause cholelithiasis has been repeatedly proved in animals (Gilbert, Mignot) and the association of infection—post or propter—with gall-stones is universally acknowledged in human pathology.

Another explanation of the mechanism by which infection causes cholelithiasis is that put forward by Hurst—namely, that as cholecystitis always sets up hepatitis (Evarts Graham), the formation of bile acids, which keep cholesterol in solution, is inhibited, and accordingly cholesterol is precipitated. Cholecystitis may be set up by micro-organisms reaching the gall-bladder wall by the blood-stream—for example, from the throat and from abscesses at the apices of the teeth; streptococci from the throat have been found to have a special selective tendency to attack the gall-bladder (Rosenow). But, generally speaking, infections of the alimentary canal, especially with virulent *B. coli*, appear to be the more common causes of cholecystitis, the micro-organisms being carried by the portal vein to the liver, excreted into the bile, and finally reaching the cavity of the gall-bladder. Thus appendicitis and cholecystitis are frequently present in the same patient, and probably the usual sequence of events is that the infection originates in the appendix and secondarily attacks the gall-bladder. It has recently been urged that latent appendicitis, in which there is no clinical history of an attack, is often the antecedent of cholecystitis (Caplesco).[1] When an operation on the gall-bladder is undertaken, the appendix is usually and rightly examined, and if diseased removed, so to speak, in the surgeon's stride; but the converse is not so frequent, and accounts for some cases in which symptoms persist after operation, because the reflex dyspepsia is partly or largely due to the irritation exerted by a chronically inflamed gall-bladder. In the past enteric fever, meaning thereby infections due to *B. typhosus* and *B. paratyphosus* A, B, and C, took a high place in the ætiology of cholecystitis and gall-stones for the following reasons: The clinical sequence was often noted, typhoid bacilli are constantly present in the bile in the disease, and they have been demonstrated in the calculi. But there is a reaction against this view, for enteric fever has become comparatively rare in this country, and gall-bladder affections are, if anything, more frequently recognised. Blaxland[2] found a history of enteric fever in 5 per cent. of a series of 100 cases in Norwich; Chauffard[3] in 19 per cent. of 166 cases in Paris. In America, where enteric fever was until comparatively recent years common, a history of that disease would naturally be higher in all patients; at the Johns Hopkins Hospital, among 888 cases of gall-bladder disease, 28 per cent. gave a history of enteric fever (Blalock).[4] Infections are prone to occur in the puerperal state, and this is one, but not the only or chief, cause of the frequency of gall-bladder disease in women who have borne children.

Rovsing[5] from examination of 530 cases of gall-stones found that 314 were sterile, and believes that infection of the gall-bladder is always secondary to the presence of gall-stones, and further, that when infection has once occurred it persists and does not die out. He thus meets the obvious criticism which the adherents of the inflammatory theory might bring against his results—namely, that failure to cultivate organisms from the gall-bladder does not prove that there has never been any infection.

(2) The biochemical or metabolic theory that there is an increase in the cholesterol content of the blood and so in the bile, and that thus pure cholesterol calculi are produced (Aschoff and Bacmeister): but by damaging the gall-bladder and reducing its resistance to infection these originally aseptic calculi may be indirectly responsible for the production of the commoner calculi as mentioned above. Experimentally Rous, McMaster, and Drury have aseptically produced showers of small calculi composed of organic debris and calcium carbonate and calcium-bilirubinate in sterile bile; and it has been suggested that in man simultaneous formation of multiple calculi occurs from metabolic or chemical alterations in the composition of the bile—a critical deposition. This is supported by the very large number—the record at present appearing to be 14,000 (Schackrev)—of small calculi all of about the same size.

The origin of the blood cholesterol is of interest in connexion with the prevention of gall-stones. Like uric acid, it may be either endogenous—namely, produced in the body, or exogenous and taken in as a constituent of foods, especially brains, yolk of eggs, and fats. The organs of the body richest in it are the central nervous system, the cortex of the adrenals, and the corpora lutea. Sixty years ago Flint of New York considered that it was formed in the brain, and so passed into the circulation; Chauffard's pupils, Laroche and Grigaut,[6] in 1913 disproved this by experiment. Chauffard, Laroche, and Grigaut[7] believe that cholesterol is formed in the adrenal cortex and the corpora lutea, especially of pregnant women who have to supply the fœtus with large quantities of cholesterol for its nervous tissues, whereas Landau and McNee[8] regard the undoubted accumulation of cholesterol in the adrenal cortex in arterio-sclerosis, and in the corpora lutea as deposits and as an index of the cholesterol content of the blood. The extent of the endogenous origin of cholesterol is thus open to question.

The cholesterol content of the blood varies much with the amount taken in food, but in normal persons it is difficult to induce a permanent well-marked increase in the amount of cholesterol in the blood, and thus suggests that there is a metabolic mechanism which maintains an equilibrium in this respect. But disorder of the fat metabolism, like that of protein and carbohydrate metabolism in gout and diabetes, may well exist and lead to a retention of cholesterol in the body. In this connexion it may be noted that gall-stones are not infrequently hereditary. Any inherited disability to deal with the metabolism of fats would, of course, render the subject specially prone to develop cholesterolæmia when on a diet containing much cholesterol. Such a diathesis helps to explain differences in the racial incidence of gall-stones—common in German women, rare in Russians, Indians, and Japanese. A high cholesterol content of the blood may also depend on diminished excretion; thus in hepatic insufficiency, especially in obstructive jaundice, the amount in the blood is usually increased, and in chronic cases deposits, or tophi, of cholesterol—xanthomas—may occur, a process analogous to uratic tophi in the gouty; the familiar arcus senilis, the sparkly synchises in the vitreous humour, and the white spots of albuminuric and diabetic retinitis are also regarded as deposits of cholesterol. In the form of slight cholecystitis known as "the strawberry gall-bladder," from the contrast between the reddened background and the yellow specks due to collections of cholesterol in the mucosa, it is unsettled whether the cholesterol in the villi is absorbed from the gall-bladder bile or deposited from the blood. But by whatever route the cholesterol reaches the inside of the villi it seems probable that detachment of these cholesterol-laden villi provides the nuclei of future multiple calculi. Aschoff suggested that women after delivery, who are prone to show a high cholesterol content of the blood, are particularly likely to develop gall-stones if they do not suckle their babies and thus fail to excrete fats in their milk.

To sum up, it may safely be stated that both these ætiological factors of gall-stones—the infective and the metabolic—are operative, sometimes one alone, probably more often both together, the infective factor being enforced and assisted by the metabolic; both therefore must be taken into account in the prophylactic measures and the medical treatment.

Prophylactic or Preventive Treatment.

From the point of view of the infective causation it is obvious that focal infections, such as pyorrhœa, dental caries, enlarged tonsils, suppuration in the accessory nasal sinuses, and appendicitis should be removed or otherwise cured. In enteric fever, in which the bile in the gall-bladder contains typhoid or paratyphoid bacilli though cholecystitis is relatively infrequent, it is well to give during convalescence hexamine for its bactericidal action. The rationale of the hexamine treatment of gall-bladder infections requires a few words of explanation, and may conveniently be dealt with here; hexamine is not itself an antiseptic, but in an acid medium it gives off formaldehyde which is; as the bile is not acid it is not at first sight clear how the administration of hexamine removes experimental infection of the biliary system, as shown by Crowe,[9] how it sterilises the infected bile from a biliary fistula, and how it appears to act beneficially in cholecystitis. There has, therefore, naturally been some scepticism as to the real value of hexamine in biliary infections, and indeed De Edes,[10] though not dealing with gall-bladder infections, concludes, as the result of a rather elaborate chemical research, that there is not any good evidence for the use of hexamine orally or intravenously as a systemic antiseptic in various diseases and localised infections. Recently, however, Knott[11] has shown that in infected bile the bacteria produce around them sufficient acid to liberate formaldehyde. A large quantity, according to Crowe[12] 75 grs. daily, of hexamine is required to disinfect the gall-bladder and bile-ducts; but amounts far short of this often irritate the urinary bladder causing frequent micturition so as to interfere with sleep and the patient's comfort, and sometimes even hæmaturia. As the vesical irritation is due to the liberation of formaldehyde in acid urine, Hurst[13] gives sufficient citrate of potassium to keep the urine alkaline and thus obviates this troublesome result, finding that eventually as much as 90 grs. daily can be given.

From the biochemical or metabolic aspect of causation, prophylactic measures should be directed to the restriction of foods rich in cholesterol in patients prone to develop a high cholesterol content of the blood as the result of pregnancy and recent enteric fever. The foods in question are yolk of eggs which contain the closely allied body lecithin, brains, and fats such as cream, butter, bacon, pork, stews, fried fish, goose, duck, sweetbreads, liver, kidneys. Vegetables, with the exception of beans and peas which are fairly rich in phylocholesterol, and meats, skimmed milk, carbohydrates and sugar which are so valuable in keeping up and restoring the nutrition of the liver cells, may be taken; but with regard to the last it must be remembered that obesity should be guarded against. Food should be taken at comparatively short intervals and in small amounts, as this leads to frequent evacuation of the gall-bladder. Over-eating should be prevented and exercise as far as possible insisted on. A lax condition of the abdominal walls should be met by breathing and other exercises.

Medical treatment is, of course, not so radical or so satisfactory as the surgical removal of the calculi and the gall-bladder which when symptoms occur is almost always infected and inflamed. Attempts to dissolve gall-stones cannot be regarded as likely to succeed. Calculi have been introduced into healthy gall-bladders of animals and observed to disappear, but there is serious doubt whether this observation can be applied to man, for these experiments were performed on dogs (Harley and Barratt; Bain, von Hansemann) in which the cholesterol content of the bile is low, and further, human gall-bladders are usually infected and inflamed. Olive oil certainly dissolves gall-stones in a test-tube, but the administration of olive oil by the mouth cannot reach the gall-bladder. There is a fallacy about the supposed success of the treatment by olive oil given orally, namely, that the altered oil—crystals of the fatty acids—may be regarded as softened calculi. Some of the good clinical results ascribed to olive oil may be due to the inhibition of hyperchlorhydria accompanying the reflex gastric disturbance due to the gall-bladder irritation. Oleic acid has been regarded as a cholagogue, and oleate of sodium is sometimes given in order to increase the flow of bile and so lead to solution of the cholesterol of the calculi by the bile acids. But of the numerous drugs at one time or another spoken of as cholagogues bile salts are the only certain ones; salicylate of sodium, which is often given with this object, benzoates, chloral, and vitamin extract of yeast, though stated by some, cannot be regarded as proved to be true cholagogues; bile salts are given in a cachet and capsule. Lyon's method of non-surgical drainage of the gall-bladder by aspiration through a duodenal tube, after spraying the duodenal papilla with magnesium sulphate solution to relax Oddi's sphincter at the lower end of the common bile-duct, appears to be admirably adapted for the relief of cholecystitis. In other respects the general treatment is on much the same lines as the prophylactic measures.

THE FIRST AND LAST KINK.

By Sir W. Arbuthnot Lane, Bart., C.B., F.R.C.S.

A quarter of a century has elapsed since I described this condition and called the attention of the profession to what I believe to be by far the most important evolutionary structure in the human body which has ever been observed, and one which is productive of very disastrous consequences.

I was led to the discovery and appreciation of the importance of this structure by a study of the changes which the body undergoes when its mechanical relationship to its surroundings is altered from the normal. I found that the human anatomy bears a simple definite mechanical relationship to its surroundings and varies rapidly with any change in that relationship. This I demonstrated in the clearest manner possible in the dissecting room of Guy's Hospital by the examination of the dead bodies of labourers who had been engaged during their lives in various arduous occupations. A careful investigation of the changes which their structure underwent in consequence of the special functions performed showed me that they were so characteristic, so definite, and so precise, that from an examination of the anatomy of these labourers I was able to determine with absolute accuracy the life-history of the individual, or in other words, the functions he performed during his life-time.

Laws Governing Changes in Structure.

The laws which I formulated as governing these changes are quite simple, and can be readily understood by a study of these labour conditions.

They are: (1) The skeleton represents the crystallisation of lines of force; (2) pressure produces definite changes; (3) strain produces definite changes; and (4) without the presence of pressure or strain an old mechanism may be altered or an entirely new one developed. The resulting changes develop to meet the altered mechanical relation of the individual to his surroundings and economise the expenditure of nerve and muscle energy.

The principles which govern the mechanical relationship of the organism to the gastro-intestinal tract which is inside the body differ in no particular from those that influence its behaviour in its mechanical relationship to surrounding objects. *Precisely* the same laws apply in both instances.

The consequences which result from the habitual overloading of the end of the large bowel with at least 24 hours' accumulated contents (a condition which is practically universal in our state of civilisation and is recognised as being normal), are met on the part of the organism by an attempt to control the excessive dilatation, distension, and elongation of the portions of the intestine which are affected by that accumulation. The effort to establish this control is usually more or less successful, but the degree of success attained varies with the vitality of the individual. The attempt to control these changes consists in the formation of acquired firm, strong bands or membranes simulating peritoneum in appearance. These develop along the lines of strain on the under surface of the mesentery. They gradually secure, contract, and shorten up the mesentery of the iliac colon and finally grip the bowel itself, rotate it on its longitudinal axis, and eventually fasten it to the floor of the iliac fossa. The alteration in the functioning of this portion of the intestine which results from the formation of these bands and their mechanical effect upon the mobility of the intestine lead to a corresponding degree of interference with the passage of material through the anchored and obstructed bowel. In civilisation the consistence of the contents of this portion of the large bowel is almost always firm and may be often quite hard. This fact again increases still further the difficulty which is experienced in the passage of the fæcal matter through the obstructed segment of bowel.

The "First and Last Kink" and its Consequences.

Here I would again remind you of another law which I have formulated—namely, that all changes that ensue in the body from an endeavour on the part of the organism to establish a mechanical relationship to abnormal surroundings at first serve a useful purpose, but later tend to shorten the life of the individual. In no instance is this law so true and so clearly illustrated as it is in the case of what I call the "first and last kink." The effect upon the entire gastro-intestinal tract is in the first instance simply mechanical. Later it results in the contamination by septic organisms of the nutrient material dammed back and stagnating in the small intestine and stomach and in the terrible sequence of the innumerable morbid sequelæ which ensue in consequence of these mechanical and toxic conditions. When I first called attention to this kink and its consequences the less observant and more conservative section of the profession denied their existence, and some isolated members, with that lack of courtesy which is so often associated with a corresponding want of comprehension, asserted that the kinks did not exist in the patient's body, but were present only in my brain.

The more intelligent section of the medical profession looked for and investigated the several kinks I had discovered and finding them began by debating their origin. Some believed that they were produced by inflammation, since they could not conceive an acquired band or adhesions arising in any other way. Others considered that they were congenital. Many observers, while recognising them, were of opinion that they did not exert any control over the passage of the contents through the anchored bowel. The simple manner in which they come about was not realised, for the obvious reason that the very definite changes which the body undergoes when its mechanical relationship to its surroundings are altered from the normal had received little or no attention from the profession.

The Atonic Variety of Obstruction.

While in a considerable proportion of cases the organism has sufficient vitality to form these bands and to effect an obstruction limited to this area in a number of feebler subjects owing to a want of formative capacity, either no bands are developed or they are not sufficiently strong and rigid to secure the colon which escapes from their controlling influence. In consequence, the lower bowel becomes enormously elongated and distended. The puddling in the pelvis of this elongated and dilated distal portion of the colon produces a degree of obstruction to the passage of solid contents through it which is increased by straining in the effort to expel the motion. It is important to realise that the obstruction so produced is often much greater than that brought about by the limited and localised obstruction caused by the acquired bands forming the first and last kink. The consequences of this type of obstruction differ definitely from those produced by the kink in that throughout the length of the proximal intestinal tract little or no effort is made to control the elongation and distension of the colon, small intestine, and stomach, so that the ulceration and cancer of the large bowel, duodenum, and stomach, so common in the case of the first and last kink due to a definite local constriction, do not occur. On the other hand, in this type, which may for convenience be called the atonic variety, the infection of the food-supply which is accumulated in much greater quantity in the elongated dilated bowel, the consequent intestinal auto-intoxication, and the changes resulting from it form a very much more marked feature. All the mechanical changes I described have been confirmed radiologically by Dr. Jordan, who has studied the subject so closely for many years. They have also been fully verified in every detail by Dr. Mutch by his accurate and careful investigations in the post-mortem room on the bodies of patients who died of cancer in the wards of Guy's Hospital.

Disastrous Sequelæ.

I need hardly again remind you of the disastrous sequelæ of the obstruction of the colon, either by the formation of bands or by an excessive elongation of its terminal segment. Briefly, they are inflammation of the mucous membrane of the tract, ulceration, first simply septic and often later cancerous at the several areas exposed to constant impact or strain, infection of the intestinal contents, the contamination of the food-supply of the body, the flooding of the circulation with organisms, toxins, and other poisonous bodies, and the deterioration of the cells of every tissue in the body, rendering them liable to the invasion of the organisms of innumerable diseases. As the result of my observations, which have now extended over many years, I am exceedingly impressed by the sequence of cancer and intestinal stasis. In my opinion these are two factors in the causation of cancer as we see it in civilisation—namely, the mechanical and the toxic.

I have observed cancer imposed on the mechanical and toxic results of chronic intestinal stasis so frequently that I am convinced that the sequence is not a mere chance. I have been equally impressed by the absence not only of cancer, but of all the other direct and indirect results of stasis as we see them in civilisation in such communities as do not suffer from chronic intestinal stasis.

Treatment.

The principles governing the treatment which I now adopt in these several conditions differ in no detail from those I formulated 25 years ago.

In the milder cases of obstruction the lubrication of the canal and the consequent softening of the intestinal contents by the free use of paraffin on the principle of the flushing tank are sufficient to meet the disability resulting from a moderate degree of obstruction. Suitable diet, kaolin and belladonna are most helpful adjuvants in that they control the spasm of the inflamed bowel and help to reduce the infection of the food-supply.

In more marked obstruction the freeing of the anchored bowel by the careful separation from it and from its mesentery of the evolutionary bands, and the accurate covering by peritoneum of any raw surface which may be left as the result of such separation, restore the structure and mobility of this portion of the bowel to the condition which existed at birth and permits of the free passage of material through the liberated loop. The results of such a simple proceeding is very often extraordinarily striking, the sufferer being frequently restored to health and to the full enjoyment of life with wonderful rapidity.

In most cases this procedure can be effected if the surgeon is perfectly familiar with the arrangement of the bands, but in a certain proportion, owing to the extent of the acquired adhesions, it is difficult and in some few instances impossible to cover accurately any remaining raw area by peritoneum. When this is the case the bowel is very liable to become fixed again by inflammatory adhesions to the floor of the iliac fossa, and in consequence does not function properly.

When the obstruction to the passage of the intestinal contents is not due to acquired bands, but to an extreme elongation of the lower segment of the bowel, such disability can only be met by dividing the ileum and introducing it into the side of the pelvic colon or by means of a colectomy. As the elongation and prolapse of the rest of the gastro-intestinal tract occurs in the feeble subject and is consequent upon the obstruction in the end of the drainage scheme formed by the very elongated and tortuous termination, to hope to remedy this condition of so-called visceroptosis by sewing up the prolapsed and dilated viscera is obviously futile, since the elongation of the pelvic colon which is the cause of the accumulation of material with its consequences must remain. I do not propose to discuss here the treatment of the ulceration of the gastro-intestinal tract and the other conditions which result from the presence of the first and last kink, but wish merely to call your attention to the enormous importance of recognising the causal relationship of all the troubles in the proximal bowel and of the deadly and far-reaching results of the intestinal auto-intoxication necessarily associated with it.

In order to obviate the development of the changes I have described, the public must be taught the necessity of evacuating the large bowel three times a day. In the first instance, this can only be secured by correct diet and suitable exercise. When the condition of obstruction already exists artificial means must be employed in addition to diet, &c.

The time has come when the medical profession must study the whole question of chronic intestinal stasis thoroughly, and realising its importance must endeavour by educating the people in proper habits and diet to obviate this acquired state which may almost be regarded as the normal in civilisation.

In view of the generally acknowledged steady increase in the disease and death-rate produced directly and indirectly by stasis, I feel I cannot urge you too strongly to take the matter in hand in earnest and with the least possible delay.

NEW DISEASES FOR OLD.

BY SIR THOMAS HORDER, BART., M.D., F.R.C.P.

DISEASES have their natural histories just as races of men and of animals have theirs, and to note the rise and fall, and how the characters change from time to time, is an interesting study. No doubt a study fraught with possible practical value also, though the difficulties of the investigation are great. So great indeed that before we can hope to arrive at any helpful conclusions we shall have been compelled to steer between the rocks of so many fallacies that when we emerge it is rather uncertain if we are still pursuing a useful course. These fallacies are much more marked in relation to the diseases to which I am going to make reference to-day than they are in relation to some others of a simpler kind, concerning which the facts collected by the Ministry of Health cover most, if not all, of the questions at issue. There is the fallacy of altered nomenclature. There is the larger fallacy of the more accurate diagnosis that comes with added knowledge and more exact methods. And there are other fallacies.

It is not my purpose to deal with my subject statistically. I have therefore not availed myself of the ready help that is always afforded to any student working along these lines by my friend Sir George Newman. Nor shall I deal with diseases which are mainly epidemic and endemic in their incidence. For here, in spite of the researches of the epidemiologists, we are at present very much on the knees of the gods, who give us, it is true, new lamps for old, but do not always benefit us thereby; cholera and typhus have gone, small-pox is going, but influenza and encephalitis have appeared and are still hovering near in no decadent fashion.

I am going to content myself by a few references to some common diseases concerning which I have seen conspicuous changes during the past 25 years, and ask you to consider with me what these changes may mean and what lessons we can possibly learn from them. It does not follow, of course, that you have seen similar changes in your country; if not, so much the more chance is there of our discovering the causes, since we may strike certain differential factors that will go far to explain them.

I.—Certain diseases have become much less common; in some of these the explanation is not difficult to find, in others it is not easy. The fall in the incidence of such diseases as diphtheria, typhoid fever, erysipelas, hydrophobia, anthrax, and glanders—to name a few only in this group—is doubtless a testimony to the ceaseless energy of the Ministry of Health and of its army of medical officers. The comparative rarity of lead poisoning and of several other industrial diseases may be reasonably attributed to the sound operation of the Factory Acts. It is fair to assume that the infrequent appearance nowadays of hydatid disease and of some allied parasitic conditions is the result of greater cleanliness in the preparation of foodstuffs for the market and more thorough inspection at the large centres of distribution.

There are some diseases whose relative infrequency to-day may be attributed to a betterment of the general conditions of life and changes for good in the habits of the people. Some forms of tuberculosis come into this category and rickets in all probability also. It has been suggested that the disappearance of chlorosis both from the out-patient rooms of the hospitals and from private practice is explicable in the same way, though here we must exercise caution lest we omit some unknown factor, seeing that we were never very certain of the main ætiological elements in this condition when it was a very common disease. Acute articular gout seems to be much less frequent now than formerly, though whether this is due to our drinking less alcohol, or to drinking different alcoholic beverages from our fathers, is not clear. Writing as late as 1920, McCrae states that gout appeared to be on the increase in the United States, but perhaps the Amendment XV. to the Constitution had not yet had time to assert a beneficent influence in this matter.

II.—Turning to the opposite side of the picture, we find very rife amongst us a series of disease-processes which lack the precision of some of those which I have just named, and for this very reason are all the more baffling when we come to consider their complex ætiology. I say complex because that seems to me the one clear fact about them when we regard them from the viewpoint of pathogenesis. In this sense they resemble our modern life itself, the dominant note of which, if it have one, is surely complexity. A feature that is common to all of them is the large element of functional disturbance that characterises them. In this series there come to be mentioned neurasthenia in all its forms; arterial hypertension with arterio-sclerosis in close attendance; enteroptosis; functional heart affections, with myocardial defects as accompaniments or sequels; hyperthyroidism and other endocrine disturbances; and in this same group we may place diabetes, since there is little doubt as to the definite increase in the incidence of this disease.

It may be urged that the reason why these names bulk more prominently in our nosological tables to-day than formerly is because our means of diagnosing them are better than they were a quarter of a century ago. But seeing that acceptance of this view of things means an acknowledgment that our own teachers were less astute clinicians than we ourselves are, I and any who were as fortunate as I was in this respect can scarcely subscribe to it. The more carefully we read the writings of the masters who immediately preceded us, and the more we recollect their words, the more certain it becomes that they were observers much too keen to miss these clinical pictures had they presented themselves with that frequency with which we see them to-day.

III.—And now I want to consider briefly another and quite different group of diseases in which, as it seems to me, changes have taken place over the period which I am considering. I refer to certain common diseases in which the factor of pyogenetic microbic infection is prominent. I spoke just now of the fall in incidence of typhoid fever and of erysipelas amongst other acute infections. These two diseases are caused by highly pathogenic members of the coliform and streptococcal groups of microbes respectively. At the same time that these particular infections have decreased there has been a notable increase in infections due to less pathogenic members of the same two groups of organisms. In the case of the coliform group we have watched the appearance of paratyphoid infections and, what is more significant, we have seen a large increase in infections due to colon bacilli or lactose-fermenting members of the coliform group. Many of these cases are subacute, and many are chronic. Infections of the urinary tract and of the gall-bladder have become very common. Of late years there are reasons to think that some bacteriæmias and diffuse intestinal infections, closely simulating paratyphoid, have been due to the colon bacillus, since expert bacteriologists have failed to obtain any other organism in the cultures from these cases or any serological evidence of typhoid or paratyphoid infection.

In the case of the streptococcus group of organisms a similar and no less striking change has been observed. The incidence of infections by *S. pyogenes* vel *hæmolyticus*, such as erysipelas, puerperal septicæmia, &c., has diminished. But we have in place of these a large increase in infections by the salivary and fæcal types of streptococci—i.e., *S. viridans*, many of them subacute and many of them chronic. The increase in the cases of bacterial endocarditis, nearly all of them subacute and associated with these feebly pathogenic strains of streptococci, is a notable example. Then there is the large group of cases of what we conveniently term "focal sepsis," chronic infections for the most part of the periodontal membrane, the tonsils, the nasal sinuses, the respiratory and digestive tracts; most of these are due to these same saprophytic strains of streptococci. These cases have become a conspicuous feature in modern medicine. Even if we admit the possibility of our more expert methods of clinico-pathological diagnosis being responsible for many individual cases in this class, this does not account for the fact that the anatomical lesions, and the clinical pictures, were not observed with nearly the same frequency 20 years ago. Nor have there been any considerable changes in bacteriological technique in this connexion during the past 15 years.

IV.—It is interesting to speculate as to the meaning of this fall in incidence of the more highly pathogenic infections and the rise in incidence of infections caused by organisms more closely allied to, or actually identical with, the saprophytic organisms of the body. If we define a microbic disease as being the sum-total of the changes produced by the interaction of an infecting microbe and the body tissues we can co-relate these changes with differing grades of virulence on the part of the microbe and with differing degrees of resistance on the part of the tissues. And it has become the custom to speak of comparative degrees of virulence of the organism and of comparative degrees of resistance of the host as the basis of any discussion of the varying course taken by diseases of microbic origin. Nor have we any more helpful hypothesis at present. Now there is no evidence for regarding the fall in incidence of the more pathogenic infections as being due to an increase in resistance on the part of the host; the evidence all goes to show that the fall has been due to those preventive measures already referred to. Nor is there any evidence for considering the increase in focal sepsis and in subinfections generally as being due to an increase in the virulence of the causative organisms; the streptococci obtained by blood culture in cases of septic endocarditis, for example, do not kill mice—a recognised test of pathogenicity in the case of streptococci. It follows, therefore, that we have good reason to regard these saprophytic infections as resulting from lowered tissue resistance. The question arises: Are we becoming more and more the prey to our own saprophytes? And if so, why? To the first question

I incline to answer, Yes. To the second question I have no answer, and yet I would like to suggest a possible answer.

Looked at from the viewpoint of disease, the conditions of modern life have probably in every respect save one tended to eliminate diseases or to render diseases less harmful. But this exception is a very significant one; the nervous and emotional strain of living has undergone a very great increase during the past two decades, and I cannot help feeling that it is perhaps in this direction we must look for the explanation of the facts I have stated, if facts they be. Consideration of exactly how it transpires that nerve strain tends so to lower tissue resistance as to render the body more prone to subinfection by saprophytic organisms and cause these infections to persist would cause me seriously to transgress the time at my disposal. But there is one point I should like to mention. Lowered resistance to microbic infection is usually regarded as being due to an ill-defined change in the patient's general state, for which we use rather meaningless expressions such as being "run down." The question I wish to raise is whether the central nervous system may not have some more definite and direct bearing upon infection, or rather upon immunity, than has hitherto been thought likely. The function of immunity is one of enormous value in the preservation of health and of life; its mechanism is also, as we know, one of a very elaborate kind. Is it not improbable that so vital and so complex a function as the protection of the body from microbic invasion and conquest should have been left, in the course of evolution of nerve control, without appropriate provision, even if it have not, as have so many other important functions, its special "nerve centre"?

Be this as it may—and the problem must be left pending exact observation and experiment—I do suggest that the influence of the nervous system upon the way we receive and respond to bacterial infection has been too little regarded, and should receive more attention.

I think that our experience of those few tense years of the Great War confirms the view that nerve stress and strain constitute a serious ætiological factor in the prevalence of microbic subinfections. For this period was followed directly, not only by a large number of cases of neurasthenia, of endocrine disturbances, and of cardiac derangements, but also by a great many cases of infection of the type we are accustomed to associate with lowered resistance. There were the cases of pulmonary tuberculosis of an insidious and smouldering type which we had not previously seen in any numbers. More pertinent to my previous remarks, there were a considerable number of cases of insidious endocardial infection by streptococci of a low grade of pathogenicity. These cases have been under very skilled observation during the past decade. In a good many of the patients the aortic cusps were infected and yet there has been no evidence of previous damage by rheumatism, syphilis, gonorrhœa, or even trench fever. But for the knowledge that these men had undergone a period of intense nerve strain we should be wholly without an adequate explanation of their slow submission to invasion by the saprophytic cocci of their own mouth or intestine. And do not the conditions which constituted a factor in pathogenesis of great importance during those few fateful years give us a clue to the problem of which I have been speaking? Did not the war achieve in a concentrated fashion what the conditions of twentieth-century life are tending to achieve, more slowly, but with equal surety, in those in whom the direct strain of war service has not operated?

If there be any truth in all this, what is the line that therapeusis should take in regard to these morbid processes? The answer seems unavoidable: That we must concentrate more upon the means of raising general resistance and especially of raising nerve tone. Perhaps we are still focusing our efforts too much upon the bacteriological part of the problem; I incline to think that we are. The response to specific inoculation, for example, in many of the cases of subinfection of which I have been speaking, *pace* certain immunisators who still retain their enthusiasm, is certainly disappointing. To instance the type-case once more: No amount of bacterio-therapy, however carefully devised and ingeniously carried out, has thus far served to change the dogged course of infective endocarditis, nor to avert the almost certain tissue. Nor does chemo-therapy to-day offer any better hope. Indeed, if we treat these patients on much the same lines as we have for many years now been treating patients suffering from pulmonary tuberculosis, give them open air by day and by night, sunlight, ample and good food, and general tonic measures—aiming by non-specific means to raise their general resistance—the response, meagre though it still is, is on the whole better than is obtained by the most up-to-date programme of bacterio-therapy. But it is clearly in the realm of prophylaxis that we must work if we want to get results, rather than in that of curative treatment, though less lethal diseases than the one just cited, but also illustrating the same point, give us better opportunities of help in regard to curative measures also.

On the basis of these remarks, whether we consider the group of modern diseases of functional type to which I made earlier reference, or whether we regard these cases of microbic subinfection with which I have dealt rather more fully, the moral is one and the same; we ought to do our best to induce our patients to return to a simpler life. We must not only point out more and more clearly and insistently the importance of hygienic rules for the conduct of the bodily functions, but in the sphere of the intellect, and especially of the emotions, we must preach moderation and simplicity. It is difficult for any clear-thinking doctor to avoid the conclusion that the hustle of modern life, the pace at which we go, the nerve strain involved, and the expense of spirit entailed, have become a large factor in the incidence of disease, and of diseases of a different type from many with which we were formerly acquainted. We have new diseases for old, but the doctor's function remains the same: to study closely his patient and to husband and to exploit to the best end all his resources. As a fellow student and as a colleague, I offer you these few remarks for your indulgent criticism.

ADDISON'S ANÆMIA AND SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD.

BY ARTHUR F. HURST, M.D.

THOSE of us who have the good fortune to be attached to one of the older hospitals of London have the inestimable advantage of doing our daily work in surroundings hallowed by a great tradition. There would be something lacking in the imagination of a man who is not stimulated by working in a hospital like Guy's, in which Astley Cooper and Hodgkin, Addison and Bright, Gull and Wilks, have made their epoch-making discoveries. I like to think that it is the spirit of Thomas Addison still pervading the hospital in which he laboured a century ago that has urged successive generations of Guy's physicians to interest themselves particularly in the disease of the suprarenal glands which bears his name, and in the form of anæmia, badly called pernicious, which he was the first to describe.

During the 18 years I have been on the staff of Guy's Hospital my male beds have been in the ward named after this great physician. It seems to me appropriate that in the short time at my disposal to-day I should give you a summary of the investigations carried out during the past five years by my colleagues and myself on Addisonian anæmia and the spinal degeneration with which it is so often associated.

In 85 per cent. of cases of Addison's anæmia symptoms or signs of nervous disorders develop, and the changes in the spinal cord upon which they depend are identical with those present in subacute combined degeneration. In the latter disease evidence of Addison's anæmia is always present sooner or later, and there can be no doubt that the anæmia and spinal cord degeneration are simply manifestations of the same infection.

This infection begins in the mouth in the form of pyorrhœa or some other streptococcal condition. Normally the free hydrochloric acid of the gastric juice makes a very efficient antiseptic barrier, which prevents bacteria, and especially streptococci, which reach the stomach from the mouth from gaining access to the duodenum. In every case of Addison's anæmia complete achlorhydria is present, and we have found that the same is true in subacute combined degeneration of the cord. This achlorhydria is an essential predisposing factor; it is not a result of the disease, as in several cases it is known to have existed ten or more years before the onset of the anæmia. It is generally constitutional in origin and often familial, thus explaining why Addison's anæmia may occur in several members of a family or subacute combined degeneration in one and Addison's anæmia in others. It is occasionally acquired, as in the cases which follow the alcoholic gastritis associated with cirrhosis of the liver, and the acute cases both of true Addison's anæmia and of subacute combined degeneration which follow the achylia caused by a growth of the stomach or the artificial achlorhydria following gastro-enterostomy or total gastrectomy.

My colleague, F. A. Knott, has isolated a hæmolytic streptococcus from the duodenal contents in a large number of cases of Addison's anæmia and combined degeneration of the cord, but it is very rarely found in any other condition, even if achlorhydria is present. Addison's anæmia and subacute combined degeneration are caused by a streptococcus which has invaded the small intestine from the mouth owing to the absence of free hydrochloric acid from the stomach and which has, in course of time, acquired certain specific characters. These are the production of blood and nerve toxins. The former leads to hæmolysis and at the same time acts on the bone-marrow, causing it to produce a large type of red cell which is found in no other condition except sprue and Bothriocephalus infection.

The neurotoxin causes subacute degeneration of the lateral and posterior columns of the spinal cords. In some cases the blood poison is produced alone; more commonly neurotoxin is also produced. In other cases the neurotoxin is predominant, and the patient complains of tingling in his feet and hands, and later of ataxic paraplegia, the anæmic symptoms being comparatively slight or only developing at a later stage. But even if no anæmia is present, and the hæmoglobin percentage is 100 or more, the characteristic megalocytosis is present.

The treatment of Addison's anæmia and subacute combined degeneration will become really satisfactory when the earliest manifestations are more frequently recognised. Thus, if the blood is examined for megalocytosis in every case in which achlorhydria is discovered during the routine examination of a patient suffering from digestive disorder, and when, in addition, a test-meal is given to patients with a characteristic sore tongue, or the paræsthesia, which is the earliest symptom of subacute combined degeneration of the cord, Addison's anæmia will be diagnosed before any anæmia has developed, and with adequate treatment its development will be prevented.

Every trace of oral sepsis should be eradicated, but this must be done slowly and only after preliminary vaccination, as otherwise a large dose of toxin is set free and absorbed locally, and may give rise to severe hæmolytic or neurotoxic crises. Hydrochloric acid is given in large doses. We find that 2 dr. three times a day are required; each dose is given in 8 to 10 oz. of water, to which the juice of an orange and some sugar are added to make a palatable drink. The first dose is taken fasting an hour before breakfast, when there is no alkaline food which can partially neutralise it; the others are taken as a beverage at lunch and dinner.

A culture of *B. acidophilus* is given three times a day apart from meals, and a tablespoonful of charcoal morning and evening. An autogenous vaccine, prepared from the hæmolytic streptococcus isolated from the duodenal contents, is injected in increasing doses. In intractable cases splenectomy may help to overcome the infection. The anæmia itself can be treated by arsenic, and, when necessary, by repeated transfusion, and the spinal symptoms by exercises.

It is futile to compare the relative merits of hydrochloric acid, arsenic, transfusion, and splenectomy in the treatment of Addison's anæmia. Each has its use. It is only by a combined attack on the infection and on the results of the toxæmia that the best results can be obtained. It should be remembered that the patient has permanent achylia, and is thus in permanent danger of reinfection and consequent relapse. He should, therefore, continue with his acid for the rest of his life, however well he may be, and he should have his hæmoglobin percentage estimated every six months. If it ever shows signs of falling, another thorough search for sources of infection in the mouth or throat should be undertaken, and active antiseptic treatment of the intestine should again be given.

By means such as these we may, I think, legitimately hope that the prognosis in Addison's anæmia, which has so long been regarded as invariably hopeless, will no longer justify the term pernicious.

WEDNESDAY, JUNE 3RD.

SOME ASPECTS OF RENAL DISEASE.

By PROF. H. MACLEAN, M.D., D.SC., M.R.C.P.

SINCE the advent of biochemical methods designed to test the efficiency of the kidneys, our knowledge of renal disease has been considerably extended. Though much yet remains to be done in elucidating the ætiology and progress of various pathological renal conditions, it is now clear that, in the main, the subacute and chronic affections of the kidney may be divided into two great groups. In the first group the predominating feature is œdema—indeed, it may be the only apparent symptom. This œdema is frequently very extensive, and its general intensity and distribution at once point to the condition as one of *subacute hydræmic nephritis*. In such patients the urine, without exception, always contains a very large amount of protein. Indeed, œdema associated with a urine containing only a very small amount of protein generally has its source in some other organ than the kidney. In hydræmic nephritis of the pure type the only difficulty on the part of the kidney seems to be the excretion of salt and water; waste products are eliminated as readily as in health. Unfortunately, however, hydræmic nephritis tends frequently to progress towards a phase characterised by retention of waste products as well as œdema. At this stage the condition is practically the same as that found in *chronic interstitial nephritis*. The fact that hydræmic nephritis has such a marked tendency to pass on to what is practically the same condition as chronic interstitial nephritis is one of the main reasons why the text-book treatment of renal diseases is rather obscure, especially as regards classification. Sometimes hydræmic nephritis (the chronic parenchymatous nephritis of the text-books) is described more or less as if it were interstitial nephritis with œdema added on. If we remember that a true hydræmic nephritis tends to pass into a stage in which the symptoms ultimately become the same as those associated with chronic interstitial nephritis, it is obvious that the exact symptoms present at any given time will depend entirely on the progress of the disease towards the chronic interstitial state at that particular time. A case beginning with typical hydræmic nephritis, and without any of the symptoms associated with chronic interstitial disease, may in a few months show all the symptoms (retention of nitrogenous waste products, excretion of a urine of low specific gravity, cardiovascular and eye changes, &c.) usually taken as characteristic of the chronic disease.

Diagnosis and Prognosis in Nephritis.

Hydræmic nephritis requires no skill in diagnosis; the extreme grade of œdema and ascites suggest an examination of the urine. Protein is found to be present in *very large amount* and granular and hyaline casts are also abundant. Though the diagnosis is easy, prognosis is extremely difficult, for though many of the cases recover, a large number, on the other hand, progress more or less rapidly to death by uræmia. The ultimate result in any such case depends on the nature of the primary lesion. When this is represented by a degeneration of the kidney cell and no definite inflammatory processes are present, the outlook is generally good. Unfortunately, it is impossible to say, in the light of our present knowledge, whether or not inflammation is present in the renal substance, and so prognosis must be based on other factors. A slight increase in blood pressure, especially in diastolic blood pressure, is a suggestive omen. The clinical condition, however, frequently affords little or no clue to the real state of matters, and it not infrequently happens that the use of renal tests show the outlook to be hopeless when the general condition and symptoms of the patient might appear to indicate quite satisfactory progress. This is especially the case at a certain stage of the transition from the hydræmic or water-logged phase to the phase of definite interstitial nephritis. At this stage the œdema frequently disappears, and the interstitial changes, being yet in their early stages, produce but little in the way of obvious symptom. The patient feels well, and, cheered by the disappearance of fluid from the tissue, the medical attendant may take a hopeful view. Often later events will prove that this view was totally unjustified, but no evidence to the contrary is offered by the clinicial symptoms alone. Renal tests, however, such as those about to be described, will always give the desired information. It cannot be too strongly emphasised that this information can be obtained only by testing the efficiency of the kidney, and the practitioner who relies on general examination of the patient in such cases, to the exclusion of the more useful renal tests, will be very frequently disappointed.

In chronic interstitial nephritis again, it is a notorious fact that the patient may have no objective symptoms and yet be on the verge of coma. He may not even have albuminuria to give a hint of the condition. It is by no means uncommon, on the other hand, to see a patient who for some time has been losing weight, but in whom physical examination fails to detect any real cause for his condition. Frequently, such patients are diagnosed as suffering from tuberculosis, more especially if a slight degree of bronchitis is present, but no tubercle bacilli are found in the sputum. Many of these patients, when examined by renal tests, show quite definitely the presence of severe inefficiency of the kidneys; in short, the condition is frequently one of chronic nephritis. Without renal tests it would, in such cases, be quite impossible to diagnose the condition by the usual physical examination. A patient whom I saw recently had just spent six months in a sanatorium under the impression that her general ill-health was due to tuberculosis. The real nature of the condition was at once elicited by tests of renal efficiency. Three weeks later she died in uræmia. It is probably not yet recognised by the medical profession at large that many ailing patients complaining of general weakness and lack of energy, but without symptoms pointing to any definite disease, are frequently the victims of renal deficiency. Many such cases have come under my notice.

While it is true that the first, and, in general, most important function of the medical man is to examine his patient very thoroughly by the simpler means at his disposal, and to exhaust this examination before applying laboratory tests, it is equally true that the stickler for "physical signs" alone, who is always decrying laboratory methods, is frequently incapable of making a correct diagnosis in that large group of cases in which physical signs are either wanting or, if present at all, are ill-defined, unreliable, and erratic. In no group of diseases is this more true than in renal conditions. It may be said at once that in this group accurate diagnosis and prognosis are frequently quite impossible without the use of modern tests. Even when it is obvious that renal disease is present, the degree to which renal activity is involved can in many cases be ascertained only by biochemical tests.

Physiological Basis of Modern Renal Tests.

The functions of the kidney are of various kinds, but the chief function is the excretion of the waste products of metabolism. Since the chief end-products normally excreted by the kidney are urea, uric acid, and creatinin, it follows that any condition interfering with their excretion will result in an accumulation of these bodies in the blood. Of these products, urea is the one most easily estimated, and it is now the practice in all well-equipped hospitals to estimate the blood-urea content in suspected renal cases. Normally, the amount present varies a good deal according to age and other factors, but it must be emphasised that the usual figure of 40 mgr. urea per 100 c.cm. blood as an outside limit is frequently much too low in the case of elderly individuals. Indeed, it is not very unusual to get 50 or even 60 mgr. per 100 c.cm. blood in aged people in whom the kidneys are apparently quite efficient for their age.

On the whole, perhaps, too much attention is paid to blood-urea content in renal disease. Taken by itself the amount of blood-urea present, unless the amount is very excessive, may signify very little. The most important rule to remember is that the blood-urea may be high with quite efficient kidneys. This may be dependent on extrarenal causes which need not be discussed here. Consideration of the blood-urea alone tells us very little about renal efficiency. In every case, however, in which high blood-urea is dependent on extrarenal causes *the urine contains a high percentage of urea*. In other words, a high blood-urea, when associated with a high percentage of urea in urine, does not signify that the kidneys are diseased. *With defective kidneys a high blood-urea is always associated with a low concentration of urea in the urine.*

With the exception of the condition discussed under hydræmic nephritis, it would appear that in nephritis all the excretory functions of the kidney are, on the whole, more or less correspondingly decreased, so that the estimation of any one waste body in the blood gives a clue as to the general efficiency of the organ. The easiest body to estimate is urea, but in order that the result should be of value it is necessary to remember the points just discussed. A high blood-urea per se is not necessarily an indication of defective kidneys.

From the point of view of the general practitioner, an elaborate laboratory investigation of renal function is out of the question. He has neither time nor the practice in laboratory manipulation necessary for the attainment of reliable results. In the great majority of cases, fortunately, no elaborate investigation is necessary. I am well aware that in America and on the continent very elaborate investigations are frequently carried out on patients suffering from renal disease. The collection of specimens of urine at varying intervals after certain definite meals, with a view to ascertaining the amount of solids present in the different specimens, is one method much in vogue. Also, the various modifications of so-called water tests are extensively used. All these demand great care and attention both on the part of patient and doctor, and they are tedious to both. From time to time we have tried all these tests at St. Thomas's Hospital with the result that, in my opinion, no information whatever is to be derived from any of them beyond that which can be obtained by the simple *urea-concentration test*. This test can be carried out by any medical practitioner in a few minutes, and in the great majority of cases gives all the information that can be derived from the most elaborate methods. We have tested it in thousands of cases, and I may safely say that no information of any importance was ever afforded by any other test that was not equally well indicated by this simple one. The only other test that may sometimes be of value is the estimation of blood-urea.

Urea-Concentration Test.

This procedure is carried out as follows. The patient is told to abstain from fluid for 12 to 18 hours before the test. Generally, it is most convenient to have the test done in the morning; he is told to drink practically no fluid from lunch on the preceding day. The importance of abstaining from fluid is exceedingly great, for unless this is done the result may be misleading. When this simple precaution is taken, the test nearly always gives reliable results.

Supposing the patient has had no fluid for 14 hours and he appears for the test at 10 in the morning, the following represents the exact procedure.

10 A.M.—Patient empties his bladder. Specimen kept for analysis. Immediately afterwards he receives 15 g. of urea dissolved in 2 to 3 oz. of water.

11 A.M.—Patient empties his bladder. Specimen (labelled No. 1) kept for analysis.

12 noon.—Patient empties his bladder. Specimen (labelled No. 2) kept for analysis.

The test depends on the fact that in the absence of excessive fluid in the system, efficient kidneys will get rid of the ingested urea by passing a concentrated urine in which the percentage of urea will be high. Thus, a normal young adult will probably pass urine, containing 3 to 4 per cent. of urea or more, one hour after taking urea by mouth. On the other hand, the urine of a patient suffering from diseased kidneys may show a concentration of only 0·8 to 1 per cent. of urea or even less than this. Naturally, the exact figures found depend on various factors, but experience shows that, when tested in this way, an individual with fairly good kidneys will always pass a urine containing at least 2 per cent. urea.

Specimens of urine are taken at hourly intervals for two, or sometimes three hours, in order to avoid the possible results of the diuretic action of urea. Sometimes, in spite of the fact that little or no fluid has been taken for several hours beforehand, a comparatively large amount of urine is passed during the first hour after the ingestion of urea. This diuretic action of urea generally passes over within the first hour, so that the true concentrating power of the kidneys is frequently best indicated in the urine of the second or even third hour. The total amount of urine passed in one hour should not exceed 100 to 120 c.cm. If it is greater than this some allowance must be made, or the test must be repeated. It not infrequently happens that the specimen of urine passed by the patient immediately before taking the urea is highly concentrated as the result of abstention from liquid. If this is so, it is hardly necessary to proceed with any test, for it is obvious that the renal condition is good.

The very simplest modification of the urea test is therefore to get the patient to abstain from fluid for 14 to 20 hours, and to estimate the urea in the urine passed after this time. The actual estimation of urea can be done by the hypobromite method and requires only a few minutes. One of the most important points about the urea-concentration test is that the patient on receiving the necessary directions can carry it out in his own home. Done in this way it requires only about ten minutes altogether, as far as the medical man is concerned, and is therefore peculiarly suitable for the busy general practitioner.

This test, combined with examination of the urine for protein and such bodies as casts and red cells, will, in the great majority of cases, furnish very definite information as to the state of the renal function. In a few cases estimation of blood-urea is also helpful. In my experience, this simple method of procedure furnishes as much information from the clinical standpoint as it is possible to obtain by the more elaborate methods which take days if not weeks to carry out. It is so simple that no technical training in its application is required, and its more extensive use will undoubtedly render unnecessary many of the very elaborate methods at present in vogue.

ABSTRACT* OF REMARKS ON
GASTRO-JEJUNAL ULCER.

By A. J. WALTON, F.R.C.S.ENG.

Mr. A. J. Walton commenced by pointing out that although gastro-enterostomy has been performed for the treatment of gastric ulcers for nearly 45 years, doubt was still cast upon its value by the fear of a later onset of gastro-jejunal ulcer. Some surgeons thought this fear exaggerated, and others advocated more severe operations to avoid what they regarded as a common complication. This, he said, made accurate determination of its frequency necessary, and, quoting many authorities and their figures, he showed that among surgeons of wide experience there was remarkable unanimity in placing the frequency between 1 and 2 per cent. There had come under his own care 20 cases of gastro-jejunal ulcer, upon 11 of which he had operated himself, the figure being arrived at by careful following up. These 11 occurred in a total of 783 gastric and duodenal ulcers subjected to operation. In 631 of these the operation was simple gastro-enterostomy, from which the danger of ulcer formation following this operation might be estimated, he said, at 1·7 per cent. Of the 11 cases only one occurred after a lesser curve ulcer, the lesion being relatively much less uncommon after duodenal and pyloric ulcers. Referring to some results already published by himself, he concluded that the operation of gastro-enterostomy must not be condemned because so small a percentage of patients might be left with the dangerous complication.

The lecturer went on to consider points in the ætiology and pathology of the condition which suggested methods of prevention, and to discuss the alternative procedures of gastro-duodenostomy and partial gastrectomy, the important question whether these ulcers can occur after operations other than gastro-enterostomy, and the close relationship between the amount of acid in this gastric juice and the incidence of gastric and duodenal ulceration. Mr. Walton laid stress on the importance of following up cases which have been operated upon, stating that by careful records it is then possible to get evidence of the ulcers in their earlier stages and so to prevent perforation. He detailed certain points in his personal method of operating and submitted to the meeting the following conclusions:—

(1) Gastro-jejunal ulcer is a relatively rare complication of gastric and duodenal ulcer occurring in a little over 2 per cent. (2) Its frequency does not warrant the introduction of extensive operations for the treatment of the primary condition. (3) It is almost entirely limited to pyloric and duodenal ulcers. (4) It occurs almost wholly in the male sex, and is found in those cases in which the gastric acidity is high. (5) As a general rule it is found when the acidity after the primary gastro-enterostomy persists, this being possibly due to an anatomical variation in the distribution of the oxyntic cells in the stomach. (6) The symptoms of this complication, although slight at first, nearly always commence

---

* Publication of the full address is reserved for a later issue.

immediately after the primary operation. (7) The frequency of the condition will probably be diminished by performing the anastomosis rather higher up than usual. (8) The treatment of the established condition should be by partial gastrectomy, which will be aided by placing the stoma rather more remote from the flexure than is usual at the first operation.

COMBATING VENEREAL DISEASE IN GREAT BRITAIN BY TREATMENT OF THE INFECTED.

By Col. L. W. Harrison, D.S.O., M.B., F.R.C.P.

[After briefly sketching the history of the control of venereal diseases in England and Wales—the schemes of Scotland and Northern Ireland, he said, are on the same principle—the speaker continued :—]

In the accompanying table of statistics are a number of interesting facts from which one may gather some idea of those aspects of the scheme which are hopeful and those in which improvement is necessary The outstanding feature is the very great reduction in the number of new cases of syphilis which reported at the centres in 1924 as compared with the number in 1920, which was the peak year. As you see, in 1920 there were approximately 42,000 and in 1924 approximately 22,000.

Syphilis.

Section F of the table is an analysis of the cases of syphilis treated at St. Thomas's Hospital, showing that the average proportion of the new cases which were new infections was approximately 40 per cent. I judge from this that the centres treated approximately 17,000 new infections in 1920 and 9000 in 1924. Judging by the amount of arsenobenzol supplied to practitioners under the scheme, one would suggest that the treatment centres dealt with much more than half the cases, since the centres use more than five times as much arsenobenzol as is given to practitioners, and, altogether, I think it safe to say that the figures represent a true diminution in the number of persons who are being infected with syphilis. This impression is being strengthened by the experience of the clinics, at many of which the medical officers are commenting on the comparative rarity of cases of recent infection. Their work is mainly on cases of old-standing, who received little or no treatment before the establishment of the venereal diseases scheme and are now attending for late recurrences.

Dr. Douglas White has estimated that the army of syphilitics calculated by the Royal Commission to exist in England and Wales in 1914 must have been built up by increments of 50,000 fresh cases per annum during the preceding 33 years. It is impossible to believe that there are anything like this number of fresh infections a year now. When you consider also that before the establishment of the venereal diseases scheme the vast majority of the infected must have been left uncured and that to-day the proportion which received such thorough treatment that the serum reactions are left permanently negative is steadily increasing, it is reasonable to hope that, if an estimate of the number of syphilitics is taken 20 years hence it will disclose nothing like the proportion found by the Royal Commission. I will not go so far as to join the optimists in some other countries who boldly declare their belief that in ten years syphilis will practically have been eradicated, but I do think that in the diminution of syphilis alone we shall see results which will well justify the labour and expense of the venereal diseases scheme.

Gonorrhœa.

As to gonorrhœa, the figures are not striking. We estimate that there are about three infections with gonorrhœa to one with syphilis, and in my own centre I have found that, of the cases appearing for the first time, about 60 per cent. are instances of new infection. If this was true of all the new cases seen in the centres in 1920, about 24,000 new infections with gonorrhœa were treated at the centres and in 1924 about 19,000, while the proportion of new infections with syphilis to those with gonorrhœa which were treated at the centres in 1920 was as 1 to 1·4 and in 1924 1 to 2·1. Various factors may account for the difference in the two ratios, and it is impossible to say with any certainty if the decrease of approximately 9000 cases of gonorrhœa in 1924 as compared with 1920 was due to a diminution in the incidence of the disease or not. It is reasonable to suppose, however, that, thanks to propaganda, the general public now regards gonorrhœa much less lightly than it did, and, if this is the case, the 31,000 cases of 1924 represented a greater proportion of the infected than did the 42,000 of 1920. If this is true, the 1924 figures do mean a decrease in gonococcal infections.

The arrest in the spread of gonorrhœa by treatment is much more difficult than is that of syphilis, because there is no specific which will quickly render the patient non-infective, and success in this branch depends on the care with which the patient is treated in the late stages of the disease and the question of cure determined. More and more effort is being concentrated on this side of the question.

The number of centres providing facilities for intermediate treatment of gonorrhœa at hours which are convenient to patients is increasing steadily. By intermediate treatment we mean such treatment ordered by the doctor which can be given by, or under the supervision of, an attendant. For example, irrigation of males suffering from gonorrhœa and vaginal and cervical treatment of females. Also much more pains are now being taken by medical officers to make sure that the patient is really rid of infection than when the scheme was started. As the quality of the scheme improves so does the attendance of the patients, and although the new cases have decreased by approximately 33,000, or 30 per cent., attendances have increased by 156,901, or over 10 per cent.

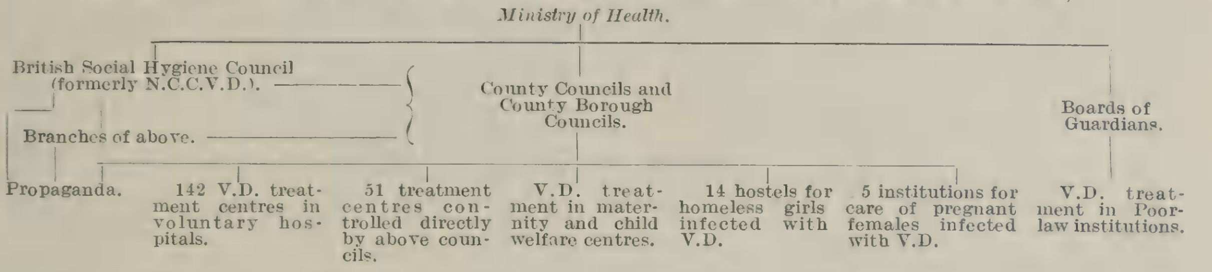
Attendance and Defaulting.

Closely connected with the question of the average number of attendances is the percentage of defaulters. It is customary with those anxious to point out the failure of free treatment to quote the percentage of defaulters shown in the annual reports of the Ministry of Health. To anyone intimately connected with the various treatment centres, as I am, and who sees the returns rendered by the centres, as I do, it is clear that the annual reports show the case in its worst light. For example, a patient with gonorrhœa who ceases attendance before completion of treatment is counted as a defaulter and would appear to be a person who is still infective. But in very many cases treatment has been continued long after all evidence of the presence of the gonococcus has disappeared, because of some persisting urethritis which seemed to be in all probability due to a secondary infection. It is unlikely that any but a very small proportion of these patients spread disease.

Often, too, patients who have been returned as defaulters turn up later and explain that they have been attending some other centre, and, in a word, the really bad defaulting, that is, of the kind which leads to spread of disease, is much less than appears from the statistics. In support, I will quote from the statistics of my own centre which, in 1924, dealt with a number of new cases equal to one-fifteenth of the new cases dealt with by all the treatment centres in England and Wales. I mark as having ceased attendance before completion of treatment all cases which at their last attendance had received any treatment, even though the record may have shown bacteriological reports which were negative for gonococci for many weeks.

A syphilitic who has not received a course of ten injections of arsenobenzol and ten of bismuth or mercury is similarly classed as having ceased attendance before receiving a course of treatment. My return for 1924 showed: Gonorrhœa cases which ceased attendance before completion of treatment, 13·02 per cent. of the cases of gonorrhœa. Syphilis cases which ceased attendance before receiving a course of treatment, 6·08 per cent. of all the cases of syphilis; and cases which ceased attendance after completion of one course but before all the treatment laid down in the programme for average cases (varying from 20 to 30 injections of each remedy, according to the nature of the case), 6·8 per cent. I doubt if those countries which have measures for searching out and punishing defaulters can show better results.

A.—CHAIN OF RESPONSIBILITY IN ENGLAND AND WALES (SCOTTISH SCHEME ON THE SAME PLAN).



Ministry of Health.
British Social Hygiene Council (formerly N.C.C.V.D.).
Branches of above.
County Councils and County Borough Councils.
Boards of Guardians.
Propaganda.
142 V.D. treatment centres in voluntary hospitals.
51 treatment centres controlled directly by above councils.
V.D. treatment in maternity and child welfare centres.
14 hostels for homeless girls infected with V.D.
5 institutions for care of pregnant females infected with V.D.
V.D. treatment in Poor-law institutions.

B.—WORK OF TREATMENT CENTRES: ENGLAND AND WALES.

Year.	New cases of—				Attendances.
	Syphilis.	Gonorrhœa.	Soft chancre.	Non-venereal.	
1920 ..	42,805	40,284	2442	19,654	1,488,514
1924 ..	22,010	31,272	1098	18,842	1,645,415

C.—PROPORTIONS OF FEMALES TO MALES.

Year.	Syphilis.	Gonorrhœa.	Soft chancre.	Non-venereal.
1920	1 to 2·1	1 to 2·1	1 to 25·8	1 to 0·8
1924	1 to 1·7	1 to 4·2	1 to 51·3	1 to 1·8

D.—PROPORTIONS OF SYPHILIS TO GONORRHŒA.

	Males.	Females.
1920	1 to 1·2 ..	1 to 1·2
1924	1 to 1·8 ..	1 to 0·7

Although the total attendances have increased, and, with them, the work of the centres, the cost of the scheme has steadily diminished until in 1923–24 the estimate was £90,000 less than in 1920–21. The cost now works out at less than 2½*d.* per head of the population.

Directions for Improvement.

I have said enough to show that the venereal diseases scheme in this country is effecting the purpose for which it was set up. Thanks to propaganda the public is daily becoming more aware of the evil effects of venereal diseases and of the importance of thorough treatment. The quality of the work in the treatment centres improves year by year so that the percentage of cases rendered non-infective increases, and we have reason for hope that in the next few years we shall see a change in the situation, which will be obvious even to the most sceptical.

The lines on which we are anxious to see a marked improvement are: Better facilities for the treatment of gonorrhœa and particularly for the intermediate treatment, that is, treatment which is carried out by or under the supervision of an attendant. It is daily, or almost daily, treatment, and to induce patients to avail themselves of it the hours at which it is available must be such as are most convenient to the patient.

Another line on which we hope to secure considerable improvement is in efforts to discover venereal disease in women and in methods of assuring their treatment. Often this must be carried out in some other place than at a treatment centre, and it is by no means always easy to arrange. Medical officers of health, however, are becoming more and more alive to the importance of this side of the question, and consequently more sympathetic to the idea of providing specially for the treatment of this class of patient.

E.—COSTS.

	£		£
1920–21	470,000	1922–23	399,000
1921–22	452,000	1923–24	380,000

Approximately 82 per cent. for treatment centres; 12 per cent. for laboratory work; 1·5 per cent. for arsenobenzol supplied to practitioners; 2 per cent. for propaganda; and 2·5 per cent. for other services.

F.—STAGES OF SYPHILIS IN WHICH PATIENTS REPORTED.

As illustrating the growing tendency of the public to seek advice early, the following figures may be quoted:—

At St. Thomas's Hospital.

	During five years ending December, 1922, out of 3065 cases of—	In the year ending April 30th, 1923, out of 601 new cases of—
Syphilis in males there were—		
Primary ..	21·3 per cent.	25·9 per cent.
Secondary	20·4 ,,	14·8 ,,
Later ..	58·3 ,,	59·3 ,,

I fear that practitioners, who are of all people the most likely to discover evidence indicative of venereal disease in their female patients, too often miss the chance of preventing further congenital syphilis in the families which they attend, by ignoring the suggestion conveyed by a series of stillbirths and miscarriages and neglecting to urge on such patients the importance of being examined and, if necessary, treated. To me it seems deplorable that so many instances should occur of a woman giving birth to one syphilitic child after another and nobody responsible for the medical care of that woman having taken the step which would almost certainly put an end to the miserable sequence.

Value of Propaganda.

Lastly, I would emphasise the importance of propaganda. Our difficulties are mainly bound up in the ignorance of the public. When they realise that no new *medical* discovery is necessary to put an end to venereal diseases and that all which is required is early and thorough treatment, we shall see the last of this scourge. It is not enough to leave the propaganda to societies. The word in season spoken by the individual goes far, and particularly so when it is spoken by the medical practitioner. The next generation of practitioners, who will be better educated in venereal disease than were their forbears, will speak the word, but why wait till then?

THE SPREAD OF CANCER OF THE RECTUM.

By W. Ernest Miles, F.R.C.S.

[After a brief description of the three clinical varieties of adeno-carcinoma, any of which might spread by direct extension through continuity of tissue, or by way of the venous or lymphatic systems, the speaker set out in some detail the anatomy of the lymphatics, in three groups, intramural, intermediary, and extramural. Dissemination by means of the extramural lymphatic system is more widespread and of much greater consequence than any other. The speaker continued:]

We may consider the extramural paths in three divisions, remembering that communications exist between them.

The Zone of Downward Spread.

The structures comprised in this zone are the perianal skin, the ischio-rectal fat, and the external sphincter muscle. Owing to the free intercommunication between the lymphatics of those structures and the efferents from the rectum, it is easy to understand how the progress of a detached cancer cell may be arrested at any point in that extensive network. It is also apparent that even an exhaustive microscopical examination of the structures above-mentioned might fail to detect such isolated cancer cells. Nevertheless, the presence of minute masses of cancer cells has been revealed in microscopical sections often enough to establish the fact beyond doubt that these structures are liable to be invaded during the process of dissemination. Additional evidence upon this point is forthcoming from clinical records in regard to post-operative recurrent growths.

In eight of my early operation cases in which a restricted type of perineal excision had been performed for primary growths situated at a distance varying from half an inch to four inches above the anal margin, recurrence took place in the perianal skin. I have also met with 16 instances of recurrent growths involving the perianal skin following perineal excisions performed by other surgeons. The perianal skin, therefore, must be regarded as being liable to involvement even in cases where the primary growth is situated in the upper part of the ampulla or as high as the recto-sigmoidal junction, and should be widely removed in every case of excision of the rectum for cancer.

I have seen post-operative recurrence in the ischio-rectal fat on 31 occasions. Seven of these followed my own perineal excisions, one occurred after an abdomino-perineal operation, and 23 followed perineal excisions performed by other surgeons. In addition to this evidence of the liability of this tissue to invasion by cancer cells, the microscope revealed the presence of a minute metastasis in the ischio-rectal fat in a specimen which I removed by my abdomino-perineal method. I have seen recurrent growths involving the external sphincter muscle upon four occasions, once after one of my own resection operations, twice after similar operations performed by other surgeons, and once after an abdomino-anal operation.

The Lateral Zone of Spread.

This area embraces the structures, the lymphatics of which enter into relation with the extensive lymphatic network between the levatores ani and the pelvic fascia. These structures are the levatores ani and the coccygei, the pelvic peritoneum, the prostate gland, the base of the bladder, the cervix uteri, and the base of the left broad ligament and the internal iliac glands.

The levatores ani are sometimes the seat of metastases. I have encountered such in the substance of the muscle close to its attachment to the rectum and also near the origin from the pelvic wall during the performance of excision operations, both primary and secondary. In one of the specimens which I removed by the abdomino-perineal method two separate plaques of growth were found in the substance of the left levator. These muscles are exceedingly prone to invasion by cancer cells, which gain access to the extramural lymphatics before the deep infiltration of the primary growth has had time to penetrate the muscular coat of the bowel, and they should, in all cases, be completely removed when a cancerous rectum is excised. I have observed plaque deposits in the peritoneum of the pelvic floor upon so many occasions that it would not be an exaggeration to say that there is not a portion of it, from the middle line to the brim of the true pelvis, that has not been implicated. This is, no doubt, due to the fact that the peritoneum in this locality is in close relationship with the extensive lymphatic network situated between the levatores ani and the pelvic fascia. A metastatic deposit in this network, therefore, speedily penetrates the pelvic fascia and extends into the overlying pelvic peritoneum. Accordingly it is essential that the peritoneum of the entire pelvic floor, as far as the brim of the true pelvis on both sides, should be removed in every case of extirpation of the cancerous rectum in which immunity from recurrence is hoped for.

The Upward Zone of Spread.

The tissues of this zone are the retrorectal (lowermost mesocolic) glands, the pelvic mesocolon in its entirety, the paracolic glands, the glands situated at the bifurcation of the left common iliac artery, and the median lumbar (aortic) glands. Since the majority of the efferent lymphatics which from the intramural lymphatic system either pass through or terminate in the structures contained in this zone, it follows that these structures constitute the principal paths by which cancer cells spread from primary growths in the rectum. In fact, this is the most constant and, therefore, the most important of all the routes of spread. We find either macroscopic or microscopic metastases scattered throughout the zone in practically all cases of cancer of the rectum, even when the growth is in an early stage of development.

In some instances the retrorectal glands are obviously enlarged and can be readily felt, but, in the majority, though the fresh specimen is carefully palpated, it is extremely difficult to be certain whether the glands are enlarged or not. Nevertheless, when these specimens have been hardened and dissected, the involvement of the glands is evident. Moreover, microscopic examination of the glands always shows one or more of them to be invaded by cancer cells. It sometimes happens that a gland may be free from deposit, although the tissues surrounding it are definitely invaded by cells. In such a case, if the glands alone were examined and found to be free from invasion, an erroneous conclusion as to the absence of extramural spread might be arrived at and a more hopeful prognosis, in regard to the possibility of recurrence taking place in adjacent structures, might be given than would be warranted had a more thorough examination been made. I have seen also carcinomatous deposits in this group of glands in a case of cancer situated at the middle of the loop of the pelvic colon, thus illustrating downward spread from that locality. The pelvic mesocolon, throughout its extent, is particularly liable to invasion. So often, indeed, is it found to be the seat of metastatic deposit that the removal of the whole of this structure in every operable case of cancer of the rectum is just as important as is thorough clearance of the axilla in breast cancer.

The part of the pelvic mesocolon which is invariably invaded is its parietal border, between the layers of which the superior hæmorrhoidal and the inferior mesenteric vessels are situated. The efferent lymphatics from the retrorectal glands accompany these vessels on their way to the glands located at the bifurcation of the left common iliac artery; and constitute the principal route by which cancer cells from the rectum are carried by the lymph stream.

At any point along this line metastases may occur, either singly or in chains.

As a rule the metastases can be felt distinctly as a chain of nodules situated in the parietal border of the pelvic mesocolon, extending as far upwards as the promontory of the sacrum. Sometimes they are too small to be palpated, and may escape detection until the tissues have been hardened and subjected to a careful dissection. Quite recently I felt obliged to abandon an abdomino-perineal operation on account of a chain of palpable metastases extending upwards along the inferior mesenteric vessels as far as the origin of that artery from the aorta. In this case there were no other visible metastases, either in the pelvic peritoneum or in the pelvic mesocolon, the primary growth involving not more than a third of the circumference, and again indicating that distant extramural spread occurs during an early phase of the disease. There is scarcely a part of the pelvic mesocolon in which, from time to time, I have not observed metastatic deposits, so that the whole of the structure must be regarded as highly dangerous tissue.

The paracolic glands, which are in series with the ano-rectal glands and are situated along the mesenteric border of the pelvic colon, are often the seat of metastatic deposit. The involvement of these glands does not proceed from one to the other seriatim as might be expected, for a continuous chain of affected glands is never seen. When a paracolic gland is found to be involved it is generally isolated, and may be situated at a considerable distance from the level of the primary growth. It is not uncommon to find an infected gland, several inches above the rectal growth, with no evidence of involvement of others of the same group. Instead of spread taking place from one paracolic gland to another, it is probable that the cancer cells first follow the course of the lymphatics accompanying the inferior mesenteric vessels and then, owing to blockage of the normal lymph stream by metastatic deposits, grow continuously or are carried by reversed flow along the lymphatic vessels of the pelvic mesocolon towards the colon to be arrested in one of the paracolic glands. When, therefore, the rectum, together with part of the pelvic colon, has been removed by a perineal method of excision it is quite possible that an infected paracolic gland, above the level of the point of section of the bowel, may have been left behind, despite the fact that a careful examination of all the paracolic glands contained in the specimen has failed to demonstrate evidence of infection. Even the extensive removal of the pelvic colon by means of the abdomino-perineal operation may sometimes fail to include an infected paracolic gland when situated many inches above the level of the primary growth.

There is ample evidence, then, that the dissemination of cancer cells by means of the extramural lymphatic system is more widespread and of much greater consequence than that which takes place in the intramural lymphatics. Moreover, it appears that, of the three zones of possible extramural spread, the upper zone is the most important, because secondary deposits are always present, visible to the naked eye, or discernible by the microscope. It occasionally happens that cancer cells are disseminated along the tissues of all three zones simultaneously. In one of my specimens the retrorectal glands were full of cancer cells, and in the pelvic mesocolon a large number of hyperplastic lymph-nodes existed along the course of the blood-vessels. Several of the paracolic glands were invaded by cancer cells. In the substance of the left levator ani muscle there were two nodes containing cancer cells, and a similarly infected node was found in the lymphatic plexus situated upon the upper surface of the muscle. In addition to these a minute metastasis was discovered in the ischio-rectal fat. This specimen is particularly interesting, because it illustrates invasion of the three zones of spread by a cancer which was still in such a clinically early stage of development that the direct extension of the primary growth through continuity of tissue had not involved the whole thickness of the wall of the bowel.

Conclusion.

As a result of (*a*) noting the position of metastases during the performance of operations; (*b*) observing the locality affected by recurrent growth either clinically or during the performance of secondary operations; (*c*) recording the extent and the position of metastases in cases in which proposed operations had been abandoned on account of their presence; (*d*) studying the post-mortem findings in regard to the spread of cancer in patients who had died from advanced and inoperable cancer; and (*e*) following the detailed examinations, macroscopic and microscopic, of specimens removed by operation, I have been able definitely to determine the tissues that are liable to metastatic deposit during the progress of the disease and to recurrence after restricted operations. These tissues are the ischio-rectal fat, the levatores ani muscles, the pelvic peritoneum, and the pelvic mesocolon, and they are directly concerned with the spread of cancer from the rectum. Pathology teaches us that they may be the seat of metastatic deposits even when the growth in the rectum is in a clinically early stage, and that unless these highly dangerous tissues are completely removed in every case in which an operation for the removal of the cancerous rectum is undertaken, post-operative recurrence will be a rule to which there will be few exceptions.

VISITS TO HOSPITALS.

THE members of the Assembly started at 2 P.M. on Tuesday, Wednesday, and Thursday to visit the various London hospitals, at which representatives had been appointed to provide a programme illustrative of the work of the institution. Tea was provided at the hospitals from 4 to 4.30, at which hour in many cases the programme came to an end, though at some of the larger centres on one or other day a lecture was given at 5 P.M. The number of visitors for whom accommodation was provided by the representatives varied from 12 to 50 from day to day at each institution, as well as with the size of the institution, the average number being 30.

St. Bartholomew's Hospital.—June 2nd: A lecture on Medical Education was given by Sir Holburt Waring at 2 o'clock, after which there were demonstrations on the Treatment of Exophthalmic Goitre complicated by Auricular Fibrillation, by Prof. F. R. Fraser and Mr. T. P. Dunhill, and on Bone Injuries (lantern demonstration), by Sir Charles Gordon-Watson. At 5 P.M. Dr. N. S. Finzi gave an X ray demonstration. June 3rd: At 2 o'clock Dr. H. Morley Fletcher gave an address on the Physicians of St. Bartholomew's Hospital, after which Dr. M. Donaldson described the technique of the treatment of carcinoma of the cervix with radium, Dr. R. G. Canti giving a histological demonstration. A demonstration by Sir Bernard Spilsbury on Criminal Pathology and a lecture on the Treatment of Diabetes, by Dr. George Graham, closed the programme. On both days visitors were invited to be present at operations by the surgical staff.

London Hospital.—June 3rd: At 2 P.M. Mr. E. W. Morris gave a lecture on the history of the hospital of which he is house governor, after which there was a demonstration of cardiac cases by Dr. John Parkinson. Other subjects brought forward were Temporary Application of a Band in the Treatment of Irreducible Spiral Fracture of the Bones of the Leg, by Sir Hugh Rigby; Intracranial Birth Injuries, their Modes of Origin, Prevention and Results, by Mr. Eardley Holland, and Methods of Determining the Efficiency of the Metabolism of Carbohydrates, by Dr. O. Leyton. June 4th: After Mr. Morris had concluded the second part of his lecture Lord Dawson of Penn, Dr. Russell Andrews, and Dr. Cecil Wall gave demonstrations of cases. Other communications were: On the Diagnosis of Intracranial Aneurysm, by Dr. George Riddoch, and the Treatment of Acute Suppurative Arthritis, by Mr. James Driberg. As on Tuesday, visitors were invited to attend the operations by the surgical staff.

Westminster Hospital.—June 3rd: At 2 P.M. Sir James Purves-Stewart gave a lecture on Clinical Examination of Cerebro-Spinal Fluid, and after the visitors had witnessed a demonstration in the pathological laboratory Dr. de Souza lectured on Hormones in Disease. At the same time there was a lecture by Prof. Stanford Cade on Surgical Anæsthesia and a demonstration of the results of facial plastic surgery by Mr. G. C. Chubb. June 4th: At 2 P.M. a lantern lecture entitled a Pot-Pourri of Medicine was given by Mr. Hildred Carlill, and this was followed by demonstrations in the electrical and ophthalmic departments, after which Prof. Cade demonstrated the technique of regional anæsthesia and Mr. Rock Carling remedial exercises. Operations by the surgical staff were conducted each afternoon.

King's College Hospital.—June 2nd: At 2.30 P.M. a lecture on Breast Hyperplasia and its Relations to Malignant Disease was given by Sir Lenthal Cheatle, and various demonstrations took place at the same hour. At 3.15 P.M. there was a demonstration in the fracture clinic by Mr. St. J. D. Buxton. June 3rd: At 2 P.M. there was a series of general surgical as well as laryngological operations, and these were followed by a lecture on Coxa Vara, by Mr. H. A. T. Fairbank.

Charing Cross Hospital.—June 3rd: From 10 A.M. till 4 P.M. there was a series of operations and demonstrations by the staff. June 4th: A similar programme was provided from 2 P.M. to 4 P.M.

St. George's Hospital.—June 2nd: At 1 P.M. operations were performed by the staff. June 3rd: At 2 P.M. operations were continued, particularly on the nose, throat, and ear, and afterwards there was an exhibition of historical and other specimens by Dr. R. Donaldson. June 4th: At 1.30 P.M. there was a further series of operations.

Guy's Hospital.—June 2nd: From 2 P.M. to 4.30 P.M. there were demonstrations and operations by the staff with visits to the wards and the various departments of the hospital. Dr. C. P. Symonds conducted the neurological demonstrations, Dr. H. W. Barber the dermatological, and Dr. H. C. Cameron the pediatric. June 4th: At approximately the same hours a similar programme was provided.

St. Mary's Hospital.—June 2nd: At 2 P.M. a lecture was given by Sir William Willcox on the Investigation and Treatment of Cases of Arthritis, and later there were operations and demonstrations by the staff, Prof. F. Langmead giving a demonstration on Sanocrysin Treatment of Tuberculosis. June 4th: At 2 P.M. there was a lecture reviewing the Treatment of Exophthalmic Goitre with special reference to the Value of Measurements of the Basic Metabolic Rate, by Dr. C. M. Wilson, and at 5 P.M. a lecture on the Colon by Sir Arthur Keith. Between these two lectures operations were performed by the staff, and Sir Almroth Wright gave a pathological demonstration.

Middlesex Hospital.—June 2nd and June 3rd: At 2 P.M. and onwards there were operations and clinical demonstrations by the staff.

St. Thomas's Hospital.—June 2nd: At 2 P.M. there were operations and demonstrations, the nerve cases being demonstrated by Dr. Farquhar Buzzard. June 3rd: At 2 P.M. operations and demonstrations were continued, among the latter being Methods of Investigating Renal Patients, by Prof. H. MacLean. June 4th: At 2 P.M. general operations and operations on the throat were followed by demonstrations, a description of the Methods of Investigating Glycosuria and Diabetes being given by Prof. MacLean.

University College Hospital.—June 2nd: At 2 P.M. operations were performed, and at 2.30 P.M. Sir Thomas Lewis demonstrated in the cardiographic department. June 3rd: At 2 P.M. operations were followed by a demonstration of the Sanocrysin Treatment of Tuberculosis by Prof. T. R. Elliott. June 4th: At 2 P.M. there were further operations and demonstrations.

Royal Free Hospital.—June 3rd: From 9 A.M. to 3 P.M. there were demonstrations and operations by various members of the staff.

Prince of Wales's General Hospital.—June 2nd, 3rd, and 4th: At 2 P.M. demonstrations were given in the general and special departments.

West London Hospital.—June 2nd, 3rd, and 4th: At 2 P.M. there were demonstrations and operations by the staff.

London Temperance Hospital.—June 4th: From 1.45 P.M. operations were performed and demonstrations given by the staff and at 5.30 P.M. Mr. Herbert J. Paterson lectured on Cancer of the Stomach.

At the *London School of Hygiene and Tropical Medicine*, *St. Peter's Hospital for Stone*, the *National Heart Hospital*, the *Samaritan Free Hospital*, the *Chelsea Hospital for Women*, the *Royal London and Central London Ophthalmic Hospitals*, the *Hospital for Diseases of the Throat*, and the *Brompton Hospital for Consumption and Diseases of the Chest*, members of the staffs gave demonstrations on different days to illustrate the methods and practice of the institutions.

The authorities of the *Central London Throat, Nose, and Ear Hospital* gave a luncheon at the Carlton Hotel before the demonstrations and operations at the clinic, an example that was followed at the London Lock Hospital.

At *St. Mark's Hospital* a feature was made of demonstrations of barium enemata; at the *Cancer Hospital* Sir James Dundas-Grant lectured on Cancer of the Throat; demonstrations were also given at *St. John's Hospital for Diseases of the Skin*. At the *Radium Institute* demonstrations were given to the visitors in batches of four by Mr. Hayward Pinch and his staff.

At the *Hospital for Sick Children*, Great Ormond-street, ward clinics were held and demonstrations on selected medical, surgical, and dermatological cases given, and visitors were present at operations.

At the *Infants Hospital* Dr. Eric Pritchard dealt with the practical management of normal and complicated cases and lectured upon Artificial Feeding.

At the *National Hospital for the Paralysed and Epileptic* operations were performed and demonstrations given by the staff, and clinical lectures by Dr. F. M. R. Walshe and Dr. Hinds Howell.

Queen Charlotte's Hospital.—There were clinical visits to the wards and a pathological demonstration on Injuries to the Fœtal Skull, by Mr. L. G. Phillips.

COMMERCIAL EXHIBIT.

An exhibition of surgical instruments and medical products, organised by the Surgical Instrument Manufacturers Association, was held in the rooms of the Medical Society of London. The following firms exhibited surgical instruments: Messrs. Allen and Hanburys, Ltd., 37, Lombard-street, E.C. 3; Messrs. Arnold and Sons, Ltd., 50, Wigmore-street, W. 1; Messrs. Down Bros., Ltd., 21, St. Thomas's-street, S.E. 1; Messrs. J. Gardner and Son, 32, Forrest-road, Edinburgh; Messrs. Mayer and Phelps, 59, New Cavendish-street, W. 1; Messrs. Weiss and Son, Ltd., 287, Oxford-street, W. 1.

British chemical and medical products were shown by British Drug Houses, Ltd., Graham-street, City-road, N. 1; Crookes Laboratories, 22, Chenies-street, W.C. 1; Mr. W. H. Martindale, 10, New Cavendish-street, W. 1.

Sir John Bland-Sutton will open the enlarged building of the East Surrey Hospital at Redhill on Friday, June 19th, at 4.30 P.M.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows :—

	£	*s.*	*d.*
Already received and acknowledged ..	458	4	0
G. W. Dawson, Esq.	2	2	0
M. S. Barfield	2	0	0
A. Graham-Stewart. (Third contribution.)	1	1	0
Anon...	1	1	0
Anonymous	1	0	0
H. E. Hargreaves	0	10	0
	465	18	0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Mental Deficiency Bill.

ON Monday, May 25th, the Mental Deficiency Amendment Bill, a measure to amend Section 7 of the Mental Deficiency Act, 1913, for the purpose of enabling a defective to be removed from an institution for the purpose of being placed under guardianship, was read a third time. On Tuesday, May 26th, the Bill was read a first time in the House of Lords.

Whitsuntide Adjournment.

The House of Lords adjourned for Whitsuntide on Thursday, May 28th, until June 16th. The House of Commons adjourned on the same day until June 9th.

HOUSE OF COMMONS.

TUESDAY, MAY 26TH.

THE PENSIONS MEDICAL SERVICES.

The House went into Committee of Supply on a vote of £41,026,000 for the salaries and expenses of the Ministry of Pensions, Mr. JAMES HOPE, Chairman of Committees, in the chair.

Major TRYON (Minister of Pensions) said that the estimated expenditure for the year 1925–26 amounted to £66,026,000, or the largest vote for any single department. It represented a decrease of about £2,858,000, or 4 per cent., on the expenditure of the previous year. The largest decrease was in the items of administration and medical expenses, which showed a total fall of 16 per cent. The cost of the medical treatment and services would, he estimated, amount to £2,847,000 for the year, compared with £3,559,000 last year. Medical treatment was naturally a declining quantity, because apart from chronic cases disabilities were inevitably and to an increasing extent reaching a condition of stability where normally no further treatment was likely to be wanted. The death-rate among disabled men remained fairly stationary at about 13 per 1000 annually, or about the same as the general population. With regard to the question of final awards, the right hon. gentleman said that the fixing of these awards did not necessarily mean that the man had wholly recovered from the injury or ailment, nor that he was in such a condition that there might not be some slight fluctuation up or down, but it did mean that a condition of normality had in medical judgment been reached. The Ministry took the very highest professional medical advice in regard to each kind of disablement before making final awards. A final award of 20 per cent. or over carried a life pension at the rate fixed. In dealing with many hundreds of thousands of cases a mistake here and there must occur, and he had taken steps to correct such cases of error. A man who found that he was worse would naturally apply for medical treatment and that treatment became the medium through which error, if there was any, was disclosed. In medical language either the diagnosis of the case might have been seriously faulty, or the prognosis of the case might have been wrong. Where either of these errors was discovered and the case was seen to have involved a serious underestimate of the normal extent of the man's disablement as a permanent matter he was able to recommend the case for further compensation under special sanction.

Mr. F. O. ROBERTS (the Pensions Minister in the late Labour Government) moved to reduce the vote by £100. He said that there was a demand for a revision and consolidation of the existing pensions regulations and he thought a Select Committee would be able to deal with all the points in connexion with these subjects. He hoped that the Minister would be able to set up such a Committee.

Mr. IAN MACPHERSON said that during three years no less than £55,000,000 was spent in medical treatment. The taxpayer was entitled to expect a return for that large amount of money and the taxpayer expected to see a reduction in the cost of these services. He did not approve of the appointment of a Select Committee. It was not the proper body for an adventure of this kind, because it was admitted that it was only a question of 20 per cent. of doubtful cases. What was the Select Committee going to do? Was it going to select other doctors to decide these cases? Every single man on a Select Committee would be predisposed to a certain line of action.

Lieut.-Commander ASTBURY referred to criticisms of the Pensions Ministry administration which he had made at question time and said that those criticisms were based on a statement which had been made to him by a medical man of standing in the Ministry, and that if the Minister would give him a letter guaranteeing that no proceedings would be taken against the man for giving the information he would give all the help he could. The Minister did not see his way to give him that letter. Now, however, his hands were to a certain extent untied because since December last this medical man had received notice to terminate his engagement with the Ministry at the end of this month, and he would be perfectly prepared if his statements were challenged to come to the House and tell hon. Members the things which he was prepared to prove. This was the statement made to him by this medical man: "Although the late Ministry of Pensions have definitely stated that no medical officer who had not seen a case would be permitted to change the amount of the award, it is the practice in some regions, notably at Burton Court, and at Manchester, for the R.A.O. to send for an assessor who has failed to reduce the required percentage of assessments during the preceding week. If, after being warned, the assessor still fails to produce the required weekly quota of reduced assessments, his services are dispensed with. As all assessors are paid on a sessional basis, they may be quietly dropped by the R.A.O. or a week's notice will terminate their agreement."

Major COHEN said that the British Legion had 3000 cases of men who could not get any benefit at all. Their contention was that if a man got a final award of under 20 per cent. and then became worse he should be entitled to make an appeal on the strength of a medical certificate signed by a qualified practitioner or by two or three practitioners. The main point was that it should be a civilian practitioner, and not one of the Ministry's doctors. He had nothing to say against those doctors, but there was no doubt that a man looked after the interests of his master, and if he was working for the Ministry of Pensions a doctor was entitled to consider the Ministry, unconsciously perhaps, more than he considered the pensioner.

Lieut.-Colonel STANLEY (Parliamentary Secretary to the Ministry of Pensions), replying to Lieut.-Commander ASTBURY, said that it was impossible for the Minister to give the undertaking asked for in regard to this medical man. If he was a man of standing in the Ministry, and knew that something directly contrary to the instructions of the Ministry was being carried out by someone in the Ministry, then it was his duty to report the fact himself and to see that it was dealt with. If he did not do so he was obviously unfit to remain in his position. If, on the other hand, he made a statement against his colleagues which was incorrect, what would be the situation in the Ministry if he were continued in his position?

Lieut.-Commander ASTBURY said that his informant was a medical man who had served in the Ministry, and had been a member of the travelling board of the pensions appeal tribunal for the last three years.

Lieut.-Colonel STANLEY said the simple fact was that this man was not an official of the Ministry. The hon. Member would not tell them who he was, and so the Minister had been forced to make inquiries for himself in the North-West Region from the regional director and the regional awards officers, who strenuously denied that any such instructions had been issued, or that any such procedure had taken place. They went further and inquired from every one of the medical assessors, and every one of them strenuously denied it. Some of them made pungent remarks with regard to the speech of the hon. Member.

Lieut.-Commander ASTBURY said these assessors were sessional men, and their engagements with the Ministry could be terminated with one month's notice, and they dared not open their mouths because they had their livings to make.

Lieut.-Colonel STANLEY said that was not the case. He was nearly as certain as he could be that no whole-time doctor under the Ministry got less than six months' notice. The Ministry were bound to accept the denials of these ten men.

Lieut.-Commander ASTBURY said that he would give the name of his informant now that he had been dismissed. He was Major Brasher, who was not only one of the most respected men, but one of the finest men who ever sat on a pensions appeal tribunal. The reason why he did not tell the hon. and gallant Member that he was a member of the pensions tribunal was because within a very short time they might have got to know who the man was who had given the information.

Medical Work of the Ministry.

Lieut.-Colonel STANLEY said he could not understand why the hon. Member should object to the Ministry knowing when it was not one of their officials. Proceeding to deal with the medical side of the Ministry's work the hon. gentleman said it was one of the pivotal branches of the pensions administration. Broadly speaking, it divided itself into two essentially different types of work. The first was the medical treatment of war disabilities, and the second was the examination and certification of pensioners and claimants. The medical and surgical branch of the Ministry had been one of the most wonderful achievements of the war. The medical profession had to mobilise all its resources and all its skill to grapple with the many problems arising out of the war. The way in which the medical profession met that demand would always be a lasting memorial to their skill and science. The policy had taken two forms: on the one hand, the Ministry had to provide special methods, and sometimes entirely new ones, for the treatment of cases caused by the war, and rarely known among the civil population. Also they had to provide accommodation for ordinary cases, so that the man who had been injured in the war should not have to wait for treatment. There was in-patient treatment, mainly in hospitals provided, owned, and controlled by the Ministry itself, but partly also in hospitals provided by voluntary contributions, and to a less extent in the ordinary civil hospitals of the country. Alongside the hospital accommodation, the in-patient treatment, had been the out-patient provision at the clinics of the Ministry. At one time the Ministry had as many as 113 hospitals and 650 clinics, and at the time when they were instituted they were an entirely new feature of public medicine. As treatment inevitably was most needed in the case of wounds and injuries—he thought that something like four out of every ten were cases of wound or injury—it was seen at a very early date that there was overwhelming necessity for supplementing both the military and civil hospital accommodation for the treatment of men who had been discharged for injuries, and this treatment did not stop short, as it did so often in the case of civil hospitals, at operative or other immediate treatment, because the medical branch of the Ministry aimed at something further than that and decided to include the whole range of orthopædic treatment. That meant the establishment of massage and electrical treatment, and also the provision of curative workshops attached to the surgical hospitals at which the more severe cases by exercising the injured limb could recover as fully as possible the use of that limb. The Ministry were running, not in addition to their hospitals, but included in the 113 hospitals he had mentioned, 15 orthopædic hospitals of their own and 60 clinics at which supplementary orthopædic treatment was given. This class of case had on the whole yielded better results than almost any other. In the course of nature these numbers were diminishing, and at the present time the Ministry was operating eight hospitals for this purpose, and 44 clinics where massage and other forms of treatment were given.

One of the most difficult classes of case were the neurasthenia cases. As regards those men who had lost their reason, they had to be shut up in county asylums according to the law. But the State saw to it that they were treated as private patients. Although it had been argued that the Ministry should itself have supplied the asylums to which these men could have been sent, he thought that there were very cogent arguments against that course. In the first place, there was the difficulty of the sub-division of the hospitals, but a much stronger reason was that the relatives of the men strongly objected to them being removed to any distance from their homes. There was a good deal of confusion between what was called neurasthenia and mental disease. Successive Ministers of Pensions, on the advice of their medical experts inside and outside the Ministry, had paid special attention to cases of nervous and mental trouble, and no expense or pains had been spared to get a man back to the normal condition. But one of the things upon which the experts were, he thought, all agreed was that the best cure for any case like that was to get a man back to his normal life and occupation as soon as possible. The great danger was that they might turn a man unnecessarily into a case that had to be certified. The Ministry had had in the past 20 neurological hospitals and 48 clinics for this purpose. The difficulty was that the Ministry had to draw very largely on those members of the medical profession who had given special study to this particular disease, and in addition they had had to train a large number of specialists of their own in order to grapple with the cases. On the whole they had been very successful, and a large number of men had been taken in time and restored to their normal condition. On the other hand, they had some cases of very serious mental trouble and disorder. The Ministry went to extremes to prevent the necessity of certifying a man, and they had several establishments to deal with border-line cases. The largest one was at Ewell. They had two establishments for certified cases, one in the north and one in the south, where selected cases were sent by agreement with the medical officers of the Board of Control. It was early days to say whether the experiment was going to be a success or not, but certainly up to date it would not justify any considerable extension of its operation.

Treatment of Tuberculosis.

As regards tuberculosis, it had already been settled to deal with that question in conjunction with the Ministry of Health, and arrangements were made for training after a man had been through his ordinary course of sanatorium treatment. He feared that that had not been quite the success that it was hoped it would be. The Ministry had no power to retain a man against his will, but further efforts were being made in another direction in conjunction with the Ministry of Health and the Ministry of Labour to see that when a man was going to be discharged, after concluding his course of sanatorium treatment or training, the medical officer of health of the locality and the employment exchange manager were notified so that everything possible might be done to get the man a job, and, if necessary, some more suitable habitation. The Ministry were spending something like £2,000,000 a year on allowances to tuberculous men. As showing the tendency for the medical branch of the Ministry's work to decline the hon. gentleman said that the day census of March, 1922, gave 119,000 in-patients and out-patients. The day census of March, 1925, gave 40,600 cases only. The general policy had been to concentrate the men in the larger hospitals and to close the smaller ones. On the whole there was a reserve of from 10 to 15 per cent. in excess of the beds occupied at any time. The same applied to out-patient treatment. At the present time they had 505 clinics which practically served the purpose of the out-patient department of a hospital. In addition to general medical practitioners in attendance, there were also specialists and the Ministry still provided for home treatment. They had spent upwards of £60,000,000 in medical treatment alone, and there had been an average of 1,750,000 cases. He thought that was a very high achievement on the part of the medical branch of the Ministry.

Dr. DRUMMOND SHIELS hoped that the Government would accept the proposal for a select committee.

Major TRYON, replying to the debate, resisted the suggestion that a Select Committee should be set up to inquire into pensions administration, but promised that he and the Parliamentary Secretary would make a full inquiry into the whole question, and said they intended to make a tour of the country to see for themselves what was being done.

On a division, the motion to reduce the vote was defeated by 279 votes to 149.

WEDNESDAY, MAY 27TH.

OVERLAPPING IN LOCAL ADMINISTRATION.

Mr. SIDNEY WEBB moved:—"That, in view of the costly overlapping of services and duplication of establishments in the various branches of public provision for the children, the sick, the aged, and the unemployed able-bodied, and as a necessary preliminary to the much-needed revision of the grants in aid in relief of the burdens now pressing so heavily on local authorities and on industry, it is essential that any measure dealing with the Poor-law should be framed, generally, on the lines of the Report of the Committee of 1917 on the Transfer of Functions of Poor-law Authorities in England and Wales; and this House accordingly urges that the Bill which it is intended to prepare and circulate to the local authorities this autumn should at least provide for a complete absorption of the existing Poor-law authorities and their functions in the county, borough, and district councils." He said that there were at least 100,000 sick persons in workhouses and union infirmaries. There were also the municipal hospitals of which there were something like 1100 maintained out of the rates as compared with 700 20 years ago, and these provided 44,000 beds. Under the Public Act Health which authorised these hospitals there was no restriction as to infectious disease; as a matter of fact they did treat a good many other cases and their cost was now something like £4,000,000 a year. There was overlapping between these two different classes of institution. A test was organised by the National Council for Social Service in 1922 in Reading and Halifax, and they found that out of 2046 cases in which boards of guardians were giving outdoor relief there were 161 in which help was also given by the maternity and child welfare service of the local authority. There were 35 cases in which the Poor-law authorities did not know that help was being simultaneously given in the form of school meals and 89 in which the Poor-law authority did not know that the unemployment benefit was being received at the same time. Boards of guardians had in 1911 very nearly 5000 medical officers costing in salaries and drugs just over £1,000,000. When the Insurance Act was passed introducing a scheme of medical attendance and drugs, which provided for practically the whole of the wage-earning population, the 5000 doctors did not diminish at all. Their number had since gone down by something like 150, but their salaries had gone up to £1,800,000. The expenditure of the local authorities which was now £1,000,000 a day would go on increasing, but any relief to the local taxpayer was out of the question, so long as they had the present overlapping and continuance of separate authorities each dealing with the same set of people and each clamouring for Government grants.

Dr. Haden Guest said he believed that on the medical side they would get quite unexpectedly good results from the abolition of the Poor-law. He wanted the medical profession to be free to use their enormous knowledge for the purpose of building up a very much healthier, better balanced, and better coördinated humanity than now existed. He spoke as a workman with an ideal, a very simple and straightforward ideal, held, he believed, by the majority of the members of his profession throughout the land. That ideal was to make science the servant of humanity and to make it go down to the depths of the life of our nation, and improve the existing conditions. At the present time it was not lack of knowledge which stood in the way of the physical improvement of children, men and women living in our cities. It certainly was not lack of sympathy or lack of money. What we did lack was simply order and the coördination of existing institutions. Our present civilisation was by no means stable. The chief danger with which we were menaced was not foreign competition, nor a future war, but that the morass of poverty in which our civilisation was foundered would rise and sap the vitality of our institutions. There was a very grave danger that the worst types of human beings grown and formed by the worst type of environment in the poorest possible parts of this country, of Europe, and of the rest of the world would gradually become the dominating factor. The human mind had a habit of turning away from things that were painful. It was too horrible to think of the suffering that went on, the mental and moral degradation, all to a large extent unnecessary. He did not believe that the existing authorities who administered the Poor-law, and the other social services, were actuated by any but the best motives; but they could not do the job. By a proper organisation of medical services they could probably diminish the amount of disease in the country by 25 per cent. By proper organisation of child life, by the medical care of it, they could go a long way to abolish the ordinary infectious diseases, such as measles and whooping-cough, which were not regarded as seriously as they should be.

Mr. Neville Chamberlain (Minister of Health) said that if he accepted the motion on behalf of the Government that did not mean that he was in any way committed to the particular recommendations. Since the report of the Committee of seven years ago a good many things had happened. He thought that they should begin by transferring administrative functions without perhaps altering the present law. It was the intention of the Government to deal with this question at the first possible opportunity. As soon as he had the main ideas formulated in his mind he proposed to discuss them with local authorities, boards of guardians, and others concerned; to circulate a draft Bill, and to invite criticism and comments upon it, and finally to place before the House of Commons something that would embody the considered views of the Government and bring this long-needed, long-desired reform to a happy and successful conclusion.

The motion was agreed to.

Deaths from Small-pox in England and Wales.

Mr. Trevelyan Thomson asked the Minister of Health the average number of deaths due to small-pox in England and Wales, and the average number of deaths due to vaccination in each of the last ten decennial periods.—Sir Kingsley Wood replied: The following are the required figures for the last seven decennial periods. Comparable figures are not available for the decennia prior to 1851–60.

Average Annual Deaths from Small-pox and Vaccination in England and Wales.

Year.	Small-pox.	Cow-pox and other effects of vaccination.
1851–60	4177	7
1861–70	3421	10
1871–80	5705	29
1881–90	1228	52
1891–1900	406	43
1901–10	429	19
1911–20	14	9

Refuse Dump at Little Britain.

Lieut.-Commander Burney asked the Minister of Health whether he was aware that London refuse was being dumped at Little Britain, in the county of Middlesex; was prejudicing the health of the inhabitants of Yiewsley; and, seeing that the local authorities of Yiewsley had no power under their by-laws to prevent this dumping, whether he was prepared to introduce a Bill during the present session taking power to safeguard the health of the public in this and similar cases.—Sir Kingsley Wood replied: My right hon. friend is aware of the case mentioned by my hon. friend. The local council have adopted by-laws to prevent nuisances from dumping, and it is proposed to discuss the application of these by-laws with them. My right hon. friend cannot at present undertake to introduce legislation on the subject.

Thursday, May 28th.

Forcible Feeding in Asylums and Prisons.

Colonel Day asked the Home Secretary whether patients in lunatic asylums were still forcibly fed; how many were so fed in the year 1924; what was the maximum number of times any one patient was so fed; how many prisoners in His Majesty's prisons were forcibly fed in the year 1924; and would he give their names and the maximum number of times any one prisoner was so fed in 1924.—Sir W. Joynson-Hicks replied: As regards the earlier parts of the question which relate to patients in asylums, I must refer the hon. and gallant Member to the Minister of Health. The number of prisoners in prisons in England and Wales who were forcibly fed in 1924 was eight. There are objections to stating the names. The greatest number of times any one prisoner was forcibly fed was 570. This prisoner is a burglar who will not take food and has to be fed forcibly three times a day. His case is entirely exceptional.

Mentally Weak Prisoners.

Mr. Rennie Smith asked the Home Secretary what arrangements were made to deal with prisoners who are found to be of weak mentality but were not certifiable as insane or mentally defective; whether they were assembled together and, if so, at which prison; how many prisoners were so assembled and how many of them were under the age of 21; whether they were long-term or short-term prisoners; and in what respect the treatment they received differed from the treatment of the ordinary prisoners.—Sir W. Joynson-Hicks replied: Male prisoners who, although not certifiable as insane or mentally defective, are unfit for the ordinary discipline of a prison, are collected in four prisons; female prisoners in three prisons. Since July 1st, 1924, 91 males, seven of whom were under 21 years of age, have been transferred to the centres from other prisons. Four females were transferred, one of whom was under 21 years of age. All were serving sentences of three months' imprisonment or more. In addition, there were at the centres 50 males and 18 females of the same class. Of these, two males and one female were under 21 years of age. These also were serving sentences of three months or more. All such prisoners in these prisons are located together under special supervision. They are instructed in such work of an industrial character as they can perform, and Brabazon classes have been arranged for those who are unfit for ordinary prison work. Outdoor labour, gardening, &c., are carried on as far as possible. The prisoners are under the observation of the medical officers and of a selected staff, and special allowance is made by the officials for the inability of the prisoners to conform to prison discipline. The prisoners receive extra facilities for exercise.

New Housing Construction.

Mr. Trevelyan Thomson asked the Minister of Health the total number of houses sanctioned this year and also during the last month by his department for erection with State subsidy under the 1923 and 1924 Housing Acts respectively.—Mr. NEVILLE CHAMBERLAIN replied: The total numbers of houses authorised from Jan. 1st to May 20th, 1925, are 35,822 under the Housing Act, 1923, and 41,942 under the Act of 1924. The latter figure includes 9000 houses which had previously been authorised under the Act of 1923. During the four weeks ended on May 20th the numbers authorised were 4706 under the Act of 1923 and 8377 under the Act of 1924, of which 3106 had previously been approved under the 1923 Act.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. R. Hughes is placed on the Retd. List with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Maj. F. W. W. Dawson to be Lt.-Col., vice Lt.-Col. R. N. Hunt, to half pay.

Maj. W. L. Hay to be temp. Capt. and relinquishes the rank of Maj.

MILITIA.

Capt. H. C. Sinderson to be Maj. and remains secd.

Capt. G. F. P. Gibbons to be Maj.

TERRITORIAL ARMY.

Capt. H. Forrest to be Maj. (Prov.).

Capt. A. J. Chillingworth (late R.A.M.C.), to be Capt.

Capt. J. Robinson resigns his commn. and retains his rank.

Lieut. P. M. Speed (late Argyll and Sutherland Highlanders) to be Lt.

Colonel E. C. Montgomery-Smith, C.M.G., D.S.O., T.D., has been appointed Honorary Surgeon to His Majesty, in succession to Colonel F. Kelly, C.B.E., T.D. (retired).

Medical News.

UNIVERSITY OF LONDON.—At a recent meeting of the Senate, Prof. E. A. Gardner, the Vice-Chancellor, being in the chair, Dr. E. C. Dodds was appointed to the University Chair of Biochemistry tenable at Middlesex Hospital Medical School. He studied at Middlesex Hospital Medical School. In 1918 he was appointed demonstrator in physiology and in 1919 senior demonstrator in physiology and pharmacology. In 1920 he was appointed assistant in the Bland-Sutton Institute of Pathology, and since 1921 he has been lecturer in biochemistry in the Institute. He obtained the diplomas of M.R.C.S., L.R.C.P. in 1921 and the degrees of M.B., B.S., with distinction in pathology and midwifery, and the B.Sc. degree by research in physiology in 1922 as an internal student, and the external Ph.D. degree in 1925. He has been a recognised teacher since January, 1923. He has published numerous papers in various scientific journals.—The title of Emeritus Professor of Bacteriology in the University was conferred on Prof. Richard T. Hewlett as from August 1st, 1925, on his retirement from the University Chair of Bacteriology in consequence of the closing of the Department of Bacteriology and Public Health at King's College.—The D.Sc. in Physiology was conferred on Mr. B. Babkin and the D.Sc. in Veterinary Pathology on Mr. A. L. Sheather. —Dr. R. A. Young was appointed representative on the occasion of the eleventh annual conference of the National Association for the Prevention of Tuberculosis to be held in London in July, and Sir Holburt J. Waring representative on the occasion of the Second Imperial Social Hygiene Congress to be held at the British Empire Exhibition at Wembley in October.—The semi-general election of medical members of the Senate for 1925–29 resulted in the appointment of the following: By Convocation—Medicine: Dr. E. Graham Little, M.P.; by Royal College of Physicians of London: Sir Wilmot Herringham; by Royal College of Surgeons of England: Mr. J. Sherren; by Faculty of Medicine: Sir Holburt J. Waring.—A course of three lectures on Blood and Circulation from the Standpoint of Physical Chemistry, will be given by Prof. L. J. Henderson (professor of biological chemistry in Harvard University) at University College, London (Gower-street, W.C.) on June 10th, 11th, and 12th, at 5.30 P.M. At the first lecture the chair will be taken by Prof. A. V. Hill.—A course of four lectures on Cardiology will be given by Dr. John Hay (professor of medicine in the University of Liverpool) at University College Hospital Medical School (University-street, Gower-street, W.C.) on June 11th, 12th, 18th, and 19th, at 5 P.M. At the first lecture the chair will be taken by Prof. T. R. Elliott, F.R.S. Admission to the lectures is free, without ticket.

ROYAL SOCIETY OF MEDICINE.—The next social evening commemorating the Charcot centenary will be held on Monday, June 15th, when Fellows and guests will be received by Sir StClair Thomson, the President, at 8.30 P.M. At 9.30 P.M. Dr. Farquhar Buzzard, President of the Section of Neurology, will give an address on Charcot and the Centenary Celebration of his Birth, and many of the works of Charcot and his pupils will be exhibited.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual conversazione of this society will be held in the Kensington Town Hall on June 12th, when Sir Humphry Rolleston, Regius Professor of Medicine at Cambridge, will deliver the Cavendish Lecture. The reception by the President of the society is at 8.30 P.M., and the lecture at 9.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—A series of post-graduate lectures will be held on Thursdays during June and July at the hospital, Marylebone-road, N.W. 1., at 5 P.M., as follows: June 11th, Mr. Aleck W. Bourne: Maternal Mortality; 18th, Mr. Trevor B. Davies: Antepartum Hæmorrhage; 25th, Mr. Louis C. Rivett: Mechanical Difficulties in Labour; July 2nd, Mr. Leonard G. Phillips: Intracranial Hæmorrhage; 9th, Mr. Lane Roberts: Clinical Features of Obstructive Labour: 16th, Mr. Leslie Williams: Toxæmia of Pregnancy.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The ninety-fifth annual meeting of this Association will be held at Southampton from Wednesday, August 26th, to Wednesday, Sept. 2nd. The President is Prof. Horace Lamb, F.R.S. Among the principal subjects of medical interest to be dealt with in presidential addresses and sectional discussions are the following: The Physiological Basis of Athletic Records; the Acquisition of Muscular Skill; Mental Law of Diminishing Returns; Health in Schools; the Inorganic Elements in Animal Nutrition; Distribution of Animals and Plants in Relation to Continental Movements. The sections will be in session severally or jointly throughout the meeting for the hearing of papers on many other subjects within their various departments.—The Leeds City Council have unanimously invited the Association to hold its meeting in 1927 at Leeds. The Association met in Leeds in 1861 and in 1890. Particulars may be obtained on application to the Secretary, British Association, Burlington House, London, W. 1.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—The eleventh annual Conference will be held on Monday and Tuesday, July 6th and 7th, in the Robert Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. On Monday at 10.30 A.M. the Conference will be opened by Sir Kingsley Wood, M.P., Parliamentary Secretary to the Ministry of Health. Three of the four sessions will be devoted to discussion of tuberculosis in childhood in which the following will take part: Prof. Pirquet (Vienna), Dr. Stanley Griffith (Cambridge), Dr. Richard Wagner (Vienna), Sir Robert Philip (Edinburgh), Dr. Clive Riviere (London), Prof. A. Louise McIlroy (London), Dr. Fergus Hewat (Edinburgh), Sir Henry Gauvain (Alton), Prof. John Fraser (Edinburgh), and Dr. Gordon Pugh (Metropolitan Asylums Board). The afternoon session on Tuesday will concern itself with the Treatment of Tuberculosis by Sanocrysin, on which Prof. Holger Möllgaard (Denmark), Prof. Knud Faber (Denmark), and Prof. Lyle Cummins (Cardiff) will speak. At the annual meeting of the Association on Monday evening films will be shown, including one recently acquired by the Association, entitled the Invisible Enemy.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On June 9th at 5.30 P.M. Sir Thomas Horder will give the opening lecture of the June to July series at 1, Wimpole-street, on Some Cases of Fever without Physical Signs.—Three special courses are continuing throughout the months—namely, in Dermatology at the St. John's Hospital; Venereal Diseases at the London Lock Hospital; and Tropical Diseases at the London School of Hygiene and Tropical Medicine.—From June 8th to 27th a special course in Gynæcology will be held at the Chelsea Hospital for Women.—The Victoria Park Hospital will hold a fortnight's course dealing with the various Diseases of the Heart and Lungs from June 8th to 20th.—From June 22nd to July 4th an intensive course has been arranged by the London Temperance Hospital.—In July there will be special courses in the following subjects: Cardiology at the National Heart Hospital; Diseases of Children at the Queen's Hospital; Neurology at the West End Hospital for Nervous Diseases; and Urology at St. Peter's Hospital for Stone. The programme of the Fellowship of Medicine, together with copies of the syllabus for each of the courses, may be obtained from the Secretary at 1, Wimpole-street, London, W. 1.

RONTGEN SOCIETY.—The annual general meeting of this society will be held on Tuesday, June 9th, at 8.15 P.M. in the British Institute of Radiology, 32, Welbeck-street, London, W. 1. A paper on Investigation of the Heart Movement by the Use of the Slit Diaphragm will be read by Dr. Robert Knox.

THE Committee of the Royal National Orthopædic Hospital, 234, Great Portland-street, London, W., has prepared plans for providing an additional 200 beds at the country branch at a cost of not less than £50,000. The present out-patient department is now "hopelessly inadequate," the total attendances last year having greatly exceeded 71,000, and plans have been laid for the extension of this department, the nurses' home, resident medical officers' quarters, and workshops at the cost of another £50,000.

RESEARCH DEFENCE SOCIETY.—The annual general meeting will be held at the house of the Medical Society of London, 11, Chandos-street, W. 1, on Tuesday, June 9th, at 3.30 P.M. The chair will be taken by Lord Lamington, and a short lantern lecture given by Dr. R. A. Lyster on Our Defences Against Small-pox.

INFANT MORTALITY IN DUBLIN.—Speaking last week at the annual meeting in aid of St. Ultan's Hospital for Infants, Dr. M. Russell, medical officer of health for Dublin, remarked that a great deal had been said about Dublin's dirty milk and the havoc it played with child life. The truth was that milk—dirty or clean—entered very little into the question at all, because most of the time the infants never got milk of any kind. Infant mortality was high in Dublin because housing conditions were such as compelled families of eight or ten persons to live in one room. According to the medical report of the hospital the percentage of illegitimate babies admitted increased from 15 per cent. in 1923–24 to 19 per cent. in the present year, and the death-rate among illegitimates increased from 48 to 54 per cent. This very high death-rate among illegitimate babies had this year raised the total death-rate in the hospital to 44 per cent., as compared with 39 per cent. in 1923–24.

DONATIONS AND BEQUESTS.—The Harrogate Town Council have made a gift of £5000 for the purchase of a site in Knaresboro'-road for a new infirmary.—Mr. John Smith, Dewsbury, bequeathed £1000 to the Dewsbury and District Infirmary.—The late Mr. William Lyall Stewart, of Edinburgh, left the residue of his property (about £30,000), subject to certain life interests, for distribution for charitable purposes in Scotland.—Mr. Alfred Dickinson, of Cedar Lodge, Sunderland, left by will £2000 for distribution among the Sunderland Royal Infirmary, the Monkwearmouth and Southwick Hospital, the Durham County and Sunderland Eye Infirmary, the Sunderland Orphan Asylum, and the Sunderland Children's Hospital.—By the will of the late Sir George Donaldson, of Grand-avenue, Hove, Sussex, the London Hospital and the Sussex County Hospital will receive £1000 each.—Among other bequests the late Mrs. Annie Eliza Clegg McCay, of Troy Hall, Londonderry, left by will £1500 to the Londonderry Eye and Ear Hospital and £1000 to the Montrose Infirmary, Scotland. The residue of the property will be divided between the Montrose Infirmary, St. Dunstan's Hostel for the Blind, and the Londonderry City and County Infirmary.—Mr. William Sillito, of Eccleshall, near Stafford, who was once a patient in the Staffordshire General Infirmary, bequeathed to this institution a legacy of over £5000.—The London Hospital has received a cheque for £60 from a man who 12 years ago was operated on in the hospital for an internal complaint. In gratitude for his recovery each year he has given a percentage of his income to help the hospital funds. The total amount contributed by him is over £500.—The Belgrave Hospital for Children has received an offer of £10,000 to assist in defraying the cost of building a new west wing on a condition that the committee of the hospital shall themselves collect another £10,000.—Mrs. Adelina Ellerton Creagh-Osborne, of Ditton Park, Slough, left £1000 to King Edward VII. Hospital, Windsor.—Blackburn Royal Infirmary has received a cheque for £500 from Mrs. Nutall, an ex-mayoress, as a thanksgiving for her restoration to health, and in recognition of the sympathy and kindness shown during her illness. Mr. W. Kay, cotton merchant, and his wife, Mrs. Kay, sent a sum of £500 in commemoration of their golden wedding, and their late son. A third gift of £100 was from an anonymous donor.—Sir Gilbert Wheaton Fox, Bart., sugar merchant, Sefton Park, Liverpool, left £1000 each to the Liverpool Royal Infirmary, the Royal Southern Hospital, Liverpool; the David Lewis Northern Hospital; the Stanley Hospital, Bootle; the Liverpool Seamen's Orphanage and the Liverpool Prison Gate Mission; £500 to the Birkenhead Borough Hospital, and £2000 each to the Liverpool Bluecoat School and the training ship *Indefatigable.*

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Friday, June 12th.

OPHTHALMOLOGY: at 8.30 P.M. (Cases at 8 P.M.)
Papers:
Mr. G. H. Pooley: The Operative Treatment of Acute and Chronic Dacryocystitis.
Dr. G. Montagu Harston: The Safety Limits of the Jullundur Operation for the Intracapsular Extraction of Cataract.
To be followed by the
Annual General Meeting:
Election of Officers and Council.

BIOCHEMICAL SOCIETY.
MONDAY, June 8th.—5 P.M. (at St. Thomas's Hospital, S.E.). *Communications:*—J. Patterson: The Carbohydrate Content of Normal Urine. H. P. Marks: Some Observations on the Testing of Insulin. R. H. A. Plimmer and J. L. Rosedale: Study of Van Slyke's Method of Analysis of Proteins. R. H. A. Plimmer and J. L. Rosedale: Experiments on Nutrition. R. H. A. Plimmer: The Action of Nitrous Acid upon Amides and some Amino Compounds. W. J. N. Burch: Some Esters of Phosphoric Acid.

MANCHESTER MEDICAL SOCIETY.
WEDNESDAY, June 10th.—4.30 P.M. (at the Manchester Royal Infirmary), Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS.
TUESDAY, June 9th.—5 P.M., Dr. S. A. K. Wilson: Disorders of Motility and of Muscle Tone with special reference to the Corpus Striatum. (First Croonian Lecture.)
THURSDAY.—5 P.M., Dr. Wilson: (Second Croonian Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street W.
MONDAY, June 8th, to SATURDAY, June 13th.—WEST LECTURE HALL, Royal Society of Medicine, Wimpole-street, W. Lecture arranged by the Fellowship of Medicine and open to all members of the Medical Profession. At 5.30 P.M., Tuesday, June 9th, Sir Thomas Horder on Some Cases of Fever without Physical Signs.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-Graduate Course in Gynæcology, lectures and demonstrations daily. Operations, pathological demonstrations. First week.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh Gardens. Tuesday and Thursday, at 2 P.M., lecture-demonstration by Dr. P. Manson-Bahr and Dr. G. C. Low.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, daily demonstrations in the O.P. Department. Bi-weekly lectures by Dr. Sibley and Dr. Whitfield.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. Post-Graduate Course in Chest Diseases. Lectures, clinical demonstrations, and laboratory demonstration.—LONDON LOCK HOSPITAL, Dean-street, W. Comprehensive Course. Daily out-patient instruction, and lectures dealing with the diagnosis and treatment of venereal diseases. Second week.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, June 8th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 3 P.M., Dr. Pritchard: Medical Wards.
WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. Bishop Harman: Eye Dept.
FRIDAY.—10 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Sinclair: Surgical out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.
SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
TUESDAY, June 9th.—4.30 P.M., Dr. J. K. C. Laing: Demonstration of Cases of Mental Disease (at the Mental Hospital, New Southgate, N.).
FRIDAY.—4.30 P.M., Mr. A. E. Giles: Treatment by Radiation in Gynæcology.
Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W. POST-GRADUATE LECTURES.
THURSDAY, June 11th.—5 P.M., Mr. Aleck W. Bourne: Maternal Mortality.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: May–June, 1925.

Clinical Lectures and Demonstrations.

Monday, June 8th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., Ocular Palsies: Mr. Williamson Noble.

Tuesday, June 9th.—2 p.m., Out-patient Clinic: Mr. Walshe. 3.30 p.m., Fractures of the Skull: Dr. Donald Armour.

Thursday, June 11th.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., The Effects of Increased Intracranial Pressure: Dr. Riddoch.

Friday, June 12th.—2 p.m., Out-patient Clinic: Dr. Gordon Holmes. 3.30 p.m., Progressive Muscular Atrophy: Dr. James Collier.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, June 8th.—12 noon, The Neuron: Dr. J. G. Greenfield.

A Course of Clinical Demonstrations will be given by Dr. H. J. Macbride, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 a.m. on Tuesdays and Fridays. The fee for this Course is £2 2*s.*

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.

Thursday, June 11th.—5 p.m., Prof. J. Joly: Radiology.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, June 11th.—4 p.m., Mr. T. Higgins: Appendicitis in Childhood.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, June 9th.—5 p.m., Dr. Sibley: Alopecia.

Thursday.—5 p.m., Dr. Whitfield: Eczema.

Appointments.

Dottridge, C. A., M.D. Camb., D.P.H., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Lyndhurst District of the County of Southampton.

Feldman, W., M.D. Lond., M.R.C.P. Lond., Medical Superintendent St. Pancras Hospital.

Hewer, C. Langton, M.B., B.S. Lond., Anæsthetist to the Hospital for Tropical Diseases, Endsleigh-gardens, N.W.

Lapage, C. P., M.D. Manch., F.R.C.P. Lond., Consulting Physician, Royal Albert Institution for the Feeble-Minded, Lancaster.

Leonard, T. M. R., Lieut.-Colonel, D.S.O., Assistant Director of Medical Service in Nigeria.

McCartney, J. Elvins, M.D., Ch.B. Edin., Director of Pathological Services to the Metropolitan Asylums Board.

Stallman, J. F. H., M.B., B.S. Lond., F.R.C.S. Eng., Honorary Assistant Surgeon, Gloucestershire Royal Infirmary and Eye Institution.

St. Thomas's Hospital: Archer, E. C., M.R.C.S., L.R.C.P. Lond., Sims, T. H., M.B., B.Ch. Camb., Rea, R. H. T., M.B., B.Ch. Camb., Alexander, R. D., M.B., B.Ch. Camb., Marks, D. P., M.R.C.S., L.R.C.P. Lond., Boggon, R. H., M.R.C.S., L.R.C.P. Lond., Robinson, A. B., M.R.C.S., L.R.C.P. Lond., and Battson, A. A., M.B., B.S. Lond., Casualty Officers and Resident Anæsthetists; Cooke, A. M., M.B., B.Ch. Oxf., Turney, H. F., M.B., B.Ch. Oxf., Walker, E. G. L., M.R.C.S., L.R.C.P. Lond., and McLean, W. W., M.R.C.S., L.R.C.P. Lond., Resident House Physicians; Hope-Simpson, J. W., M.B., B.Ch. Camb., Resident House Physician for Children; Thwaites, W. G., M.R.C.S., L.R.C.P. Lond., Gervis, W. H., M.B., B.Ch. Camb., Hudson, M. W. P., M.R.C.S., L.R.C.P. Lond., and Starkey, R. S., M.R.C.S., L.R.C.P. Lond., Resident House Surgeons; Jeffery, A. L. P., M.B., B.S. Lond., Resident Orthopædic House Surgeon; Allan, F. G., M.R.C.S., L.R.C.P. Lond., and Barron, R. McG., M.R.C.S., L.R.C.P. Lond., Resident House Surgeons; Rees, E. J., M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician; Webb-Peploe, M. H., M.B., B.Ch. Camb., Junior Obstetric House Physician; Heath, W. E., M.R.C.S., L.R.C.P. Lond., Senior Ophthalmic House Surgeon; Gordon, G. D., M.R.C.S., L.R.C.P. Lond., Junior Ophthalmic House Surgeon; Neilson, D. F. A., F.R.C.S. Eng., Cavenagh, J. B., M.B., B.Ch. Oxf., Cooper, G. K., M.B., B.Ch. Camb., Cook, L. C., M.R.C.S., L.R.C.P. Lond., Dobie, J. M., M.R.C.S., L.R.C.P. Lond., Kies, J. P., M.R.C.S., L.R.C.P. Lond., Barron, H. T., M.D. Lond., Marcano, G. R., M.R.C.S., L.R.C.P. Lond., Trim, E. A., M.R.C.S., L.R.C.P. Lond., Marriner, H. I., F.R.C.S. Edin., Robinson, J. J. R., M.R.C.S., L.R.C.P. Lond., Amesur, C. A., M.R.C.S., L.R.C.P. Lond., Gibbens, J. H., M.R.C.S., L.R.C.P. Lond., Lloyd-Williams, P., M.R.C.S., L.R.C.P. Lond., L.D.S., Lancaster, A. L., M.R.C.S., L.R.C.P. Lond., Nicholson, H. W., M.R.C.S., L.R.C.P. Lond., Thompson, E., M.R.C.S., L.R.C.P. Lond., Asserman, D., M.R.C.S., L.R.C.P. Lond., de Jersey, G. W. S., M.R.C.S., L.R.C.P. Lond., Marsden J. P., M.R.C.S., L.R.C.P. Lond., Brockman, E. P., M.B., M.Ch. Camb., F.R.C.S. Eng., Rees, D. I., M.R.C.S., L.R.C.P. Lond., Wiener, R. A. K., M.R.C.S., L.R.C.P. Lond., Tompson, B. E., M.B., B.Ch. Oxf., Shires, B., M.B., Ch.B. Edin., Chiesman, W. E., M.R.C.S., L.R.C.P. Lond., Rickman, J., M.B., B.Ch. Camb., Hodder, R. G., M.R.C.S., L.R.C.P. Lond., Haward, F. C., M.R.C.S., L.R.C.P. Lond., Crawford, D. P., M.R.C.S., L.R.C.P. Lond., Riley, D., M.R.C.S., L.R.C.P. Lond., and Guymer, R. F., M.R.C.S., L.R.C.P. Lond., Chief Assistants and Clinical Assistants.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen County.—Asst. M.O.H. £600.

Ashton-under-Lyne District Infirmary.—H.S. at rate of £150.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £175.

Birmingham, Queen's Hospital.—House Governor and Sec.

Bradford Children's Hospital.—H.S. £100.

Bristol General Hospital.—Hon. Clin. Assts.

Bristol, Southmead Hospital.—Second Asst. M.O. £200.

Cambridge, Addenbrooke's Hospital.—H.S. at rate of £130.

Cancer Hospital, Fulham-road, S.W.—H.S. at rate of £100.

Chiswick General Hospital.—Hon. S.

City of London Maternity Hospital, City-road, E.C.—Res. M.O. at rate of £100.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Dundee Royal Infirmary.—Hon. Asst. Obstetrician and Gynæcologist.

Edinburgh, Royal Hospital, Morningside.—Asst. P. £350.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. at rate of £100.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P., H.S., Cas. M.O., and Cas. Surg. O. All at rate of £100.

Hastings, Royal East Sussex Hospital.—Hon. Ophth. Surg.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. Also H.P. Each at rate of £50.

Lanchester Rural District Council, &c.—M.O.H. £800.

London Hospital.—Head of Children's Dept.

London Lock Hospital, 91, Dean-street, W.—Clin. Asstships.

Manchester, St. Mary's Hospitals.—Two H.S.'s. Each at rate of £50.

Manchester University and Royal Infirmary.—Director of Lab. of Clin. Investigations. £600.

Middlesex Hospital and Medical School, W.—Medical Registrarship. £300.

Northampton General Hospital.—Hon. S.

Oldham Royal Infirmary.—Three H.S.'s. Each at rate of £200.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Queen Mary's Hospital for the East End, Stratford, E.—H.P.'s and H.S.'s, &c.

Reading, Royal Berkshire Hospital.—One H.P. and two H.S.'s. Each at rate of £150.

St. Bartholomew's Hospital Medical College.—Lecturer on Pharmacology and Therapeutics.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Salford Royal Hospital.—H.S. to Gynæcological, &c., Depts., and H.P. Each at rate of £125.

Sheffield, Jessop Hospital for Women.—Asst. H.S. at rate of £100.

Sheffield Royal Hospital.—Res. Surg. O. £200.

West Bromwich, Union Infirmary, Hallam-street.—Visiting S.'s. £150. Visiting P., £200. Aural S., £75. Dental S., £50. Operative Obstetrician, £10 10*s.* per case.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each at rate of £100.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

Wrexham Infirmary.—H.S. at rate of £150.

Births, Marriages, and Deaths.

BIRTHS.

Aylen.—On May 29th, at Halesworth, Suffolk, the wife of John Aylen, M.R.C.S., L.R.C.P., of a son.

Coombs.—On May 26th, at Bedford, the wife of Martin Coombs, M.B., of a son.

Furness.—On May 25th, at Latham House, Melton Mowbray, the wife of Harold S. Furness, M.D., of a daughter.

Jobson.—On May 26th, at Crofton-road, Ealing, the wife of J. Stanley Jobson, M.B., F.R.C.S., of Knightsbridge, S.W., of a son.

MARRIAGES.

Scott—Godfrey.—On May 28th, at Bexley Parish Church, Kent, Joseph Wilkie Scott, *M.C.*, M.D., M.R.C.P. Lond., of Regent-street, Nottingham, to Marjory Annie Godfrey, M.R.C.S., L.R.C.P., third daughter of W. S. Godfrey, Esq., of Red House, Bexley Heath, Kent.

DEATHS.

McCarthy.—On May 24th, at Cliftonville, Margate, Justin McCallum McCarthy, M.D., M.R.C.S. (late of The Grove, St. George's, Shropshire), in his 73rd year.

Scott.—On May 29th, at a London nursing home, Dr. James Scott, of 11, Templeton-place, Earl's Court.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE SUN, THE WIND, AND THE SKIN IN THE TREATMENT OF DEEP-SEATED TUBERCULOSIS.*

BY G. R. GIRDLESTONE, F.R.C.S. ENG.

THE SUN.

THE sun offers light and heat. Their actions differ profoundly. Can we learn how and when to use each?

(*a*) *Light.*—Ultra-violet light is intensely irritating, but it is stopped by the epidermis. In small doses it stimulates, in large doses destroys, cells near the surface. The sun's rays, as their wave-length increases from violet towards red, gradually lose photochemical activity but gain penetration and heating power. Those that travel beyond the skin have little or no bactericidal action.

(*b*) *Heat.*—The skin is heated throughout its depth, the arterioles in the corium dilate, its circulation and metabolism become active. But if the heat of the summer sun is unchecked by cool and moving air, the skin and the whole body quickly get too hot. General loss of tone results, and any further roasting leads to danger.

Dangers—Light: Overdose of superficial action, sunburn; of deep action, sun fever. Heat: Overdose to the head, sunstroke; applied widely, heat stroke.

Thus we learn that free use of the sun's light without protection, or of its heat without cooling, is harmful. Fortunately a good skin provides protective pigment, and days without wind are rare.

In *superficial tuberculous lesions*, violet and ultra-violet light attack the bacilli directly.

In *rickets*, the deep action of light is sought, only small doses are needed, and the effect is excellent in unpigmented and non-pigmenting children and animals. In this condition photochemical action counteracts for the time being a deficiency in light or in diet.

Is it not possible that in deep-seated tuberculosis, as in rickets, light and cod-liver oil are only of value in cases where there has been a deficiency in light or in diet?

Where the body's normal need for light is satisfied, has its further exposure to the photochemical action of light any value in the treatment of deep-seated tuberculosis? I am inclined to doubt it for the following reasons: (1) Unless or until the skin is pigmented the optimum dose of light is small, and limited by the dangers of overdose of its superficial or its deep action. (2) Exposure to sunlight can only be advantageously increased pari passu with pigmentation. This experience suggests that the "deep" dose of light cannot be advantageously increased. (3) The sun offers light and heat, a good skin stops the light as near the surface as possible. The better the skin, and the more tropical the race, the deeper the pigmentation, and the more complete the barrier to light. (4) The best results in the treatment of deep-seated tuberculosis are obtained in well pigmented patients. They can be much longer exposed to sun and wind than those poorly pigmented, but little or no greater dose of light passes the barrier. Apparently the main value lies among the other factors of sun and wind.

If it is true that photochemical activity plays a comparatively unimportant part in the treatment of deep-seated tuberculosis by exposure of the body to the sun and the wind it is entirely wrong and very misleading to estimate the value, and calculate the dosage, of any sample of sunlight by its content of violet and ultra-violet light. The treatment of rickets and of superficial tuberculous lesions by light is a different matter; if ultra-violet light is definitely wanted, and particularly prescribed, it is an advantage to be able to dispense it accurately.

THE WIND.

The wind cools the skin by convection and stimulates it by its impact. The combination is pleasant, and, like a contrast bath, promotes active hyperæmia of the skin. The cooling induces an increased production of heat in the body. The wind also affects metabolism, rousing by its ever varying touch the sense organs of the skin, which, in their turn, are in sympathy with the deep viscera.

THE SKIN.

The skin has fallen into neglect. It is not merely an excretory organ or something which we can blister or paint with iodine. Clearly the skin is our first line of defence against invasion of the body; its efficiency in resisting bacteria is so complete that it is often forgotten. But quite apart from the cuticle, which it has developed as a physical defence, there is evidence that the skin plays an important part in our reaction to the tubercle bacillus. Both its sensibility and metabolism appear to share in this action. Most of us feel strongly that good pigmentation carries with it a better prospect of recovery, though it is a popular and dangerous fallacy to suppose that pigmentation is a sign of healing and its depth a measure of cure. Pigmentation is the response of a good skin to photochemical light; a skin capable of cutting out the violet end of the spectrum, capable also of gaining the greatest benefit from other effects of sun and wind.

THE AIR BATH.

On cloudy days it is just an air bath, on windy days a wind bath, when the sun shines it is a sun bath. The best results are obtained with the long exposures which a warm sun, a cool wind, and a well-pigmented skin allow. The maximum exposure is desirable, but its length is limited by the danger of too much light or heat or cold. In England, from October to March there is little or no danger of an overdose of light, but in the spring and summer very great care is necessary. Rollier's table, prepared to suit the Leysin sunlight, is needlessly and disappointingly slow for our mild and fickle sun. Everyone must work out a method to suit the strength of his sunlight, which varies with the latitude and the clarity of the air. Allowance must be made for different types of skin: for poor skins the dose must be reduced, while good skins will benefit by longer exposures. I entirely agree with Rollier that several short exposures are better than one long one; especially when too much heat or cold is feared. In the winter I give three or four air baths a day. In very cold weather they are each just a few seconds' exposure of the body to a douche of keen wind, never long enough to cause lasting chill. A cold bath of wind or water gives the greatest benefit when it is followed by an after-glow of the skin. I am looking for the best method of making sure of this after-glow.

I have great faith in the value of air baths all through the year. An artificial light department is not essential, perhaps not very helpful, to an orthopædic hospital.[1] For cases of rickets do splendidly with air baths and suitable diets. And I think it probable that the ordinary (mixed) English weather, applied to the skin in well-regulated doses, will be found as effective in the treatment of tuberculosis of bones and joints as other climates, and far more helpful than any indoor artificial sun.

Oxford.

THE GUARDIANSHIP SOCIETY.

THE valuable work of the Guardianship Society, which has its headquarters at Brighton, was again emphasised at the annual meeting at Brighton on May 21st. The Society has for its object the care of mental defectives and the physically infirm requiring guardianship by means of home life in contra-distinction to institution life. There is no restriction in regard to age, sex, religion, or even nature of infirmity. For 12 years it has carried on its work which has increased and developed year by year. The cases now on the books number 419. Of this total, 165 patients are boarded out under the Board of Control, and 178 are boarded out under the inspection of the Society. The others are all under observation. Many patients are visited in their own homes, and for these an occupation centre has been started, and the Society has just boarded out its first case from a mental hospital. In addition, an after-care committee is being formed for those patients discharged from mental hospitals. A few years ago the Society purchased a cottage farm in Sussex capable of the reception of seven patients. This has practically exceeded all expectations in regard to its helpfulness to the patients, and the Society is hoping to establish another similar home elsewhere when the opportunity presents itself. A new centre has been opened in Essex; and following the urging of the Board of Control that local authorities should make an effort to organise schemes of guardianship on similar lines, several local authorities are getting into touch with the Society.

At the conclusion of the business meeting an address on Public Opinion and the Mental Underling was given by Dr. H. Crichton-Miller, of the Tavistock Clinic. He dealt with his subject under the headings of prevention, education, and environment, which he described as three aspects of the great problem. With regard to the environmental aspect, Dr. Crichton-Miller stated that hitherto the mental underling had been allowed to take his chance; he had been exposed to society and society had been exposed to him; yet slowly but surely public opinion was facing the fact that this was an extremely costly proceeding, and that punishment could not improve those who could not understand. Society, therefore, he considered, was waking up to the necessity of providing special environments for those who could not be expected to adjust to a normal environment. The official solution was State-controlled institutions; some of these in America accommodated 3000. But in his view the ideal solution was that which the Guardianship Society provided—a personally-selected environment among normal people for the ineducable underling. Thus the patient was allowed to feel that he was still a part of and in touch with normal society.

---

* Opening a discussion at the meeting of the British Orthopædic Association at Oxford, on April 17th.

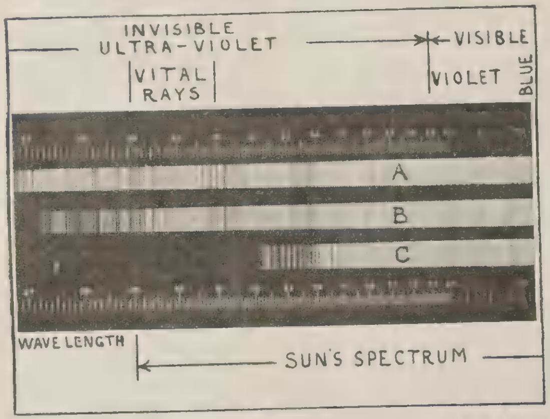
[1] Lupus presents a different problem, requiring an expensive light equipment and a specially trained staff to work it. The treatment of lupus, with its demand for experience and minute accuracy, would be far better done if the cases were concentrated. Half a dozen hospital centres for lupus (possibly attached to orthopædic hospitals as at Alton) would serve England and Wales.

AID TO MEDICAL TERMINOLOGY.

IN writing a book on "Gynecology for Nurses," Dr M. J. Seifert, of Chicago, added an appendix dealing with the roots of medical words, in order to facilitate the reading of his book. This appendix has now been republished separately, entitled "Synthesis of Medical Terminology" (London: D. Appleton and Co., pp. 30, 3*s.* 6*d.*), in the hope that it may also prove useful to students of medicine and dentistry. All the more commonly used suffixes, roots, and prefixes that are met with in medicine are given in alphabetical order, with their meaning, and examples of the way in which words are built up from them. The author enjoins the avoidance of hybrids, although, since he does not himself distinguish between Greek and Latin roots, he affords the reader no protection from coining them, He regrets the few well-established terms in medicine to which arbitrary definitions have been given and hopes that these may be eliminated by a slow process of evolution. The cultivation of the habit of analysing scientific terms, as he truly remarks, will simplify the study of any subject, and tend towards the development of a cultured and logical mind. Brief and incomplete as it is, the book will prove useful to those for whom it is intended.

LAMPLOUGH'S VITAGLASS.

THIS new window glass is the result of the scientific work of Mr. F. E. Lamplough, M.A., formerly Fellow of Trinity College, Cambridge, and for some years director of research with Messrs. Chance Brothers, who manufacture the glass for him to his formula. The glass contains a high proportion of quartz, is somewhat harder than ordinary glass, and as the accompanying illustration shows transmits freely the waves of short length beyond the visible violet end of the spectrum. Three forms of the glass are supplied. The standard form with "cathedral" surface gives slight diffusion and indistinctness of vision suitable for glazing in schools, offices, sun-lounges in hotels and houses, children's nurseries, invalids' rooms, verandah roofs and windscreens, sanatoria, hospitals, houses for animals and birds, particularly for chickens and laying poultry. A form is available at slightly higher cost with special diffusing surface for privacy. Where clear vision is specially desired, as in the lower sashes in houses, the glass is available at higher price as clear window glass. The ordinary form of the glass can be obtained at 4*s.* a square foot for small quantities from Mr. F. E. Lamplough, 47, Bunbury-road, King's Norton, Birmingham. A discount of 30 to 45 per cent. is allowed for hospitals and institutions, according to the quantity required and economy of cutting the necessary panes. The clear window glass costs 5*s.* 6*d.* per foot, subject to reduction for quantities.



Spectrum photograph, showing the composition of light from an electric arc between iron poles, taken by the Hilger quartz spectrograph. A, without screen. B, passed through vitaglass 2 mm. thick. C, passed through ordinary glass 2 mm. thick.

THE PUBLIC SCHOOLS YEAR BOOK.

THE Year Book for 1925, edited by C. H. Deane, *M.C.*, B.A., A. P. W. Deane, B.A., and W. A. Bulkeley Evans, O.B.E., M.A. (London: H. F. W. Deane and Sons, the Year Book Press Ltd., 31, Museum-street. Pp. 894. 10*s.* 6*d.*), is the official book of reference of the Headmasters' Conference and is in its thirty-sixth year of publication. For all who have charge of boys at school age it will be found a valuable compendium of information with regard to public and preparatory schools and universities, giving the names of governing bodies and staffs, the means of admission, particulars of fees and scholarships, and so forth. In addition, there are articles on the professions, the public services, and business careers which may follow school or college life, a new section having been added this year dealing with surveying, land agency, and auctioneering. The medical and dental professions are dealt with fairly but briefly, and veterinary medicine finds a place. Interesting supplements are a public schools bibliography divided into general and comprehensive works and works dealing with particular schools, a list of public schools periodicals and old boys clubs, and a list of school colours. It is a valuable work of reference.

WIRELESS FOR HOSPITAL PATIENTS.

THERE is a general belief in America, so we are informed on the good authority of the *Journal of the A.M.A.*, that the brain of the sick man or the convalescent woman functions only during periods of health. In hospital his or her mental pabulum is the inane detective story, the period sex-thriller, the novel rewritten from a movie plot, the collection of short stories, culled from cheap magazines, supplemented by the tattered and coverless issues of current magazines "prepared for the Babbittry." The position may not be as bad as that in this country, but it is safe to say that ennui is not unknown in surgical wards. The *Daily News* is appealing to its readers for funds to fix a wireless point or plug at the bedside of each hospital patient in London, and has set up a small committee to administer the fund subscribed, the members of which are Lord Knutsford, Sir Arthur Stanley, Lieut.-Commander J. M. Kenworthy, M.P., Prof. W. H. Eccles, F.R.S., President of the Radio Society of Great Britain, and Mr. J. Hugh Jones, Managing Editor of the *Daily News*. Capt. P. P. Eckersley, of the British Broadcasting Company, has agreed to advise in matters of equipment. The cost is estimated at about £1 a point, and the total outlay for 25,000 to 30,000 beds at £50,000 or more. The *Daily News* has set the lead by offering itself to equip the Royal London Ophthalmic Hospital in every detail, and the offer has been accepted by the secretary of the hospital, who writes that "to patients who are deprived of their sight (the majority, happily only temporarily) it is scarcely necessary to stress the inestimable boon and the enjoyment which will be given during the time they are undergoing treatment."

The same movement is going on in France, where Dr. Dujardin published in a recent issue of the *Echo Médical du Nord* a poem entitled "Musicothérapie," of which the two concluding stanzas run as follows:—

> Grâce au sans-fil, bientôt, de ses flots d'harmonie
> Orphée apaisera les affres, l'agonie
> Des malheureux couchés aux lits de l'hôpital
> Par l'écho d'un concert d'un brillant récital! . . .
>
> Mais épargne à leurs nerfs, confrère,—à leur cervelle,
> La musique de fous de l'Ecole nouvelle;
> D'un orchestre en fureur l'horrible tintamarre
> Pourrait les envoyer, avant l'heure. . . à Clamart!!

We are indebted to Prof. D. T. Barry for the following metrical translation:—

> And soon, thanks to wireless, Orpheus will appease
> With harmonies sweet poor souls ill at ease,
> Their anguish relieving in hospital ward,
> As echoes of concerts swift pain can retard.
>
> Consider their nerves, dear colleague, and rule
> Out the music of fools of the modern school;
> The furious jazz of some horrible band
> May send them too soon to the distant land.

HARROGATE.

THE new handbook for 1925–26 sets out the amenities of the Yorkshire spa. An outline sketch is given of the cure itself and of the sports, pastimes, and amusements, educational and other facilities offered at the resort, along with a guide to excursions on foot or otherwise, and a list of hotels and boarding-houses. The brochure on the waters and treatments of Harrogate, giving full details of the cure, may be obtained on application to the General Manager, Baths and Wells Department, Harrogate.

M. H. G.—Intra-mammary insufflation in cows consists of the introduction of air into the udder by means of a suitable syringe, the nozzle of which is inserted into the teats. These may be then closed with clips to prevent the air escaping.

Essential in the Bathroom.

VIC
TONIC
Face-cloth

not only washes the skin thoroughly free of all dust and powder; it has a tonic action which gets right down into the delicate skin tissues where real complexion beauty is built. Quite different from ordinary face-cloths, it is always hygienic, never gets "slimy," and makes the skin healthier and lovelier after every wash. Hand size 1s., Bath size 1s. 6d., in hygienic sealed envelopes.

Sole Manufacturers:
GROUT & Co., Ltd.,
Great Yarmouth.
Stocked by all leading wholesalers.

NORVIC
(Regd.)
Crêpe Binders

are invaluable in maternity and all cases where adaptability, elasticity and support are required. In 6, 8 & 11in. widths.

Oliver-Sharpey Lectures

ON THE

INTERPRETATION OF THE ELECTROMYOGRAM.

Delivered before the Royal College of Physicians of London on May 5th, 1925.

BY E. D. ADRIAN, M.D., F.R.C.P., F.R.S.,
FELLOW AND LECTURER OF TRINITY COLLEGE, CAMBRIDGE.

LECTURE I.

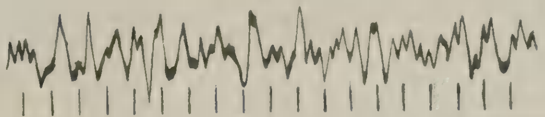
THE subject of these lectures is not one in which striking advances have been made in the last few years. It is one which raises many more questions than it solves, and it may turn out in the end to have little or no importance in practical medicine. But I believe that it is worth while to review our rather scanty knowledge, because the recording of the electromyogram is, at any rate, an additional method of investigating diseases of the muscles and nervous system, because such investigations may turn out to be of great theoretical value to neuro-pathology, and last, but not least, because they are quite easy to carry out. Prof. Einthoven's string galvanometer is now so popular an instrument of clinical research that the whole apparatus has become standardised, simple to work, and, if not cheap, at any rate not so expensive as it would have been if its use were confined to physiological laboratories. It has been used by physiologists quite as much for recording the action currents of muscles and nerves as for the slower changes in the heart. In medicine, however, its use has been confined, in this country at least, almost entirely to cardiac problems, and so far as I am aware the only extensive observations on the electromyogram which have been published here are those of Dr. Golla. In America Stanley Cobb has made several investigations of great importance, and in Germany the subject, set going by Piper in 1911, has already attracted a number of investigators and been the source of lively controversy.

TECHNIQUE.

To record the electric response in a contracting skeletal muscle only one change is needed in the ordinary electro-cardiograph outfit, and that is an increase in the speed of the recording surface. To give a clear picture of every oscillation in the record, a speed of at least 5 cm. a second is necessary, but higher speeds are well within the range of the ordinary moving plate or film cameras. Many varieties of electrode have been used, of which more anon, but a simple and quite effective form is a small zinc plate covered with lint moistened in saline and held in contact with the skin by bandages. Two such electrodes are placed over the muscle a few centimetres apart; they are connected to the galvanometer switchboard and the skin current, if any, is compensated in the usual way. The shadow of the string is now at rest as long as the muscle is completely relaxed, but any active movement produces an immediate blurring of the shadow and a photograph will show that this is due to a succession of irregular oscillations at a rate of 50–250 a second. The record of these oscillations is the electromyogram which we have to interpret (Fig. 1).

The fact that the record is that of a rapidly oscillating rather than a steady current makes it possible to simplify the technique considerably. If we wish to obtain a true record of a current in the body flowing in the same direction for a second or more, we must use non-polarisable electrodes (e.g., a zinc plate, a pad of lint soaked in $ZnCl_2$, a pad soaked in NaCl, and then the skin), and even then we may have to make allowances for polarisation in the skin itself. But as long as the currents are rapidly alternating, polarisation at the electrodes will merely distort the record slightly and will have scarcely any effect on the frequency or amplitude of the oscillations. So, if we are not on the look-out for steady changes as well as the rapid waves, it is quite permissible to make our electrodes out of metal plates bandaged directly on to the moistened skin or, better, of steel needles thrust directly into the muscle to be investigated. These needle electrodes, introduced by Rehn[1] in 1921, have the advantage of reducing the resistance in the circuit, and the much greater advantage of leading directly from the contracting muscle or from a particular group of fibres in it. The result is a much better localisation of the electromyogram to one particular region. Action currents produced in the muscle in question will have a much greater, and action currents in other neighbouring muscles a much smaller, effect on the galvanometer. With the ordinary pad electrodes the localisation is so bad that the response might be affected by almost any muscle in the limb.

FIG 1.



Tracing of electromyogram recorded from flexors of left forearm during voluntary contraction of moderate force. Upper line—shadow of string. Lower line—time marker recording intervals of 1/50 sec.

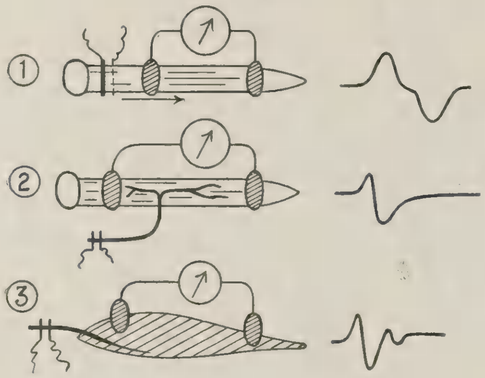
Apart from the use of needle electrodes, the only other improvement, or suggested improvement, in technique since Piper's work is the use of triode amplification to make possible the recording of very small currents. At present, however, the successful working of systems of this kind needs a great deal of care and experience if the results are to be trusted.

NATURE OF THE ELECTRICAL RESPONSE.

The record, then, consists of rapid oscillations of the string, each lasting from 1/50 to 1/250 of a second, and it seemed reasonable enough to suppose that these are due to a series of action currents in the contracting muscle, action currents, that is, of the type made familiar by the classical muscle and nerve physiology. This interpretation is certainly correct, but it is not so obvious as it appears at first sight. No doubt most of us have hazy recollections of the electric changes which accompany activity in a muscle, confused as a rule with the mysterious workings of Pflüger's law. These recollections ought to tell us that the action current of an isolated frog's sartorius is a diphasic affair, and that successive action currents never become fused with one another, so that if the muscle is thrown into a steady contraction by tetanic stimulation it will give a rapid series of diphasic action currents and a not steady effect. So far the electric response of a voluntary contraction agrees with that of an artificial tetanus in an excised muscle. But if we produce an artificial tetanus in a human muscle by stimulating its motor nerve, the excursions of the string are usually much larger than those produced by a voluntary contraction. This fact has caused some misgivings in the past, but there is not much doubt that the larger size of the artificial effect is due to the more complete synchronisation of the impulses in the different groups of muscle-fibres. Indeed, the differences there are, are exactly the differences we should expect to find on passing from the simplest case to one more complicated. The point has been discussed by Piper,[2] Hoffman,[3] and others, but certain aspects are worth re-stating.

The classical frog's sartorius is an ideal muscle for the study of the action current, because it is composed of parallel fibres, of which the majority run almost the entire length of the muscle. If it is stimulated at the pelvic end (where there are no nerve-fibres), a disturbance travels along every fibre from the stimulated point, showing itself by a thickening of the fibre—the mechanical response and a movement of ions—the electric response. The ionic movement is of such a character that if electrodes are placed on the muscle and connected together through a galvanometer, a brief current will pass through the galvanometer towards the electrode which is nearest the active region of the fibre. As the active region passes first under one electrode and then under the other, the current in the galvanometer will travel first one way and then the other, forming the ordinary diphasic response (see Fig. 2 (1)), and the rate of conduction is easily calculated from the interval between the phases and the distance between the electrodes. There are two main complications which arise when other preparations are used: (*a*) We may stimulate the nerve instead of stimulating the muscle-fibre directly (Fig. 2 (2)), and (*b*) we may use a muscle in which the two leading-off electrodes are applied to two distinct groups of muscle-fibres (Fig. 2 (3)). The effect of stimulating by way of the nerve will depend on the position of the nerve-ending in the fibre with reference to the electrodes, for a disturbance will travel out in either direction from the nerve-ending. If this lies between the two electrodes the response will be smaller because of the interference between the two phases—it may be reduced to nothing when the electrodes are equidistant from the nerve-ending, and in any case the separation between the phases will not vary in a regular way with the distance between the electrodes. A further complication is added when the electrodes are on different muscle-fibres. This must almost certainly happen with the penniform type of muscle, and it must often happen with other types, as human muscle-fibres are rarely longer than 5–6 cm. The result will be that the response to a single stimulus may become polyphasic instead of diphasic, since it is unlikely that the active regions of the different fibres will exactly neutralise one another's effect on the galvanometer circuit.

Fig. 2.



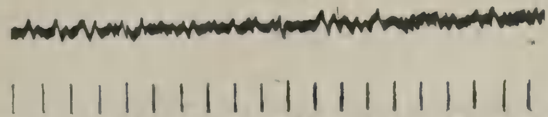
Owing to these complications the response of a human muscle stimulated by its motor nerve may seem to depart considerably from the classical diphasic action current. One muscle may seem to give much smaller action currents than another, though its contractions are no less powerful, and the response may seem to vary in an arbitrary way when the position of the electrodes is altered. The same is true of the action currents due to reflex or voluntary activity; but there is no doubt at all that the oscillations of the electromyogram are caused by the same processes as those which give the action current of the frog's sartorius.

It should be mentioned that Henriques and Lindhard[4] do not agree with the classical account of the action current as due to a change conducted throughout the muscle-fibre. They wish to substitute for it the notion of an oscillating discharge from the motor end-plate. For reasons stated elsewhere,[5] the older conception seems to be much preferable to the new, but the question need not concern us at the moment. There is a general agreement that the action current denotes the passage of an impulse into the muscle-fibre, and the exact process by which the current is produced is immaterial.

Tetanic and Tonic Contractions.

We may take it, then, that the rapid oscillations of the electromyogram are due to a rapid succession of action currents in the muscle, that the voluntary contraction is in part at least a tetanus of the same kind as that produced by repeated stimuli to the motor nerve. This has been shown more directly by actual mechanical records of muscle in voluntary contraction. The very delicate methods used recently by Hill[6] and by Athanasiu[7] (both involving the use of the string galvanometer) agree in showing that the contraction is never steady but exhibits rapid oscillation of about the same frequency as those in the electromyogram. The contraction is an incomplete tetanus in fact, in the sense that the fusion of the successive twitches is not perfect. This leads at once to one of the chief questions which the electromyogram may help to solve. The question is whether there are any contractions of central origin occurring normally or pathologically in skeletal muscles which are not of the nature of a tetanus, which are not accompanied by a rapidly oscillating action current. The answer to this question is still doubtful, though the number of investigations which have appeared on it recently makes one hope that a definite answer is not far off. The position at present is that various examples have been put forward of contractions, centrally innervated, which have appeared to go on without producing an oscillating electromyogram, but further investigation has shown that in most of these examples the oscillations can be detected if the recording system is sensitive enough, though they are often of extremely small amplitude. One such case which will serve as a good example is that of the sexual clasping reflex of the male frog. During the breeding season the forearms are maintained steadily in the clasping position for a fortnight or more, and in 1921 Kahn[8] found that the forearm muscles seemed to be quite free from action currents. Action currents appeared if the reflex was augmented by interfering with the frogs, but disappeared again as soon as the steady condition was returned to. Later researches confirmed this work and added the information that the reflex was not affected by injection of atropine or adrenalin or by section of the sympathetic.[9] Recently, however, the missing action currents have been found by Wachholder[10] and by Lullies.[11] They are extremely small in comparison with the electromyogram of a normal phasic contraction in a frog's muscle, but Lullies has made the interesting observation that the force exerted during the clasp is also very small as long as both frogs are absolutely quiet, but that the slightest stimulus causes an immediate increase both in the force exerted and in the electrical oscillations. There is, in fact, very little of the steady, continuous pressure which the appearance of the forearms suggest, but we are dealing with a reflex which appears to be continuous because it is evoked at once by the slightest movement or external stimulus. The condition suggests a comparison with a mild degree of spastic paraplegia, when the muscles are probably flaccid as long as the leg is completely at rest, but harden into "tonic" activity at once when they are moved or touched by the examiner. In spastic muscles the action current oscillations are also very difficult to detect, and some observers have denied their existence. Hoffmann, Hansen, and Weiszäcker,[12] whose technique is above suspicion, have shown that small oscillations are undoubtedly present and that they increase when the tension exerted by the muscle increases. It would be surprising if this were not so, for in decerebrate rigidity the extensor muscles give the typical oscillating electromyogram (Fig. 3), and the close relation between decerebrate rigidity and spastic paraplegia is too well established to be set aside. The presence of the oscillating response in decerebrate rigidity was described by Dusser de Barenne and Buytendick,[13] and has been confirmed repeatedly. It is an observation of fundamental importance, for it shows that in a contraction which is usually taken as an example par excellence of a tonic postural reflex, there is the same intermittent excitation which is found in the ordinary tetanus. This does not exclude the possibility that there may be some steady excitation of another kind, occurring at the same time and giving rise to no electrical effect but augmenting the contraction of the muscle. This suggestion has often been made on account of the small metabolic exchange, the absence of fatigue in tonic postural reflexes, and the presence of sympathetic as well as ordinary motor nerve-fibres running to the muscle. The relatively feeble electrical effects combined with strong contractions in spastic muscles might seem to favour the idea of a feeble tetanus superimposed on a steady background of some other kind of contraction, but, unfortunately, the electrical effects really give us little information one way or the other, because the amplitude of the electric oscillations may depend on many factors which are not necessarily related to the force of contraction. It is true that in the frog's sartorius Watts[14] has compared the tension developed in a single twitch with the amplitude of the electric response, and finds a linear relation between the two, and this is the relation we should expect if changes in the force of the twitch depended simply on changes in the number of muscle-fibres in action. But if we measure the diphasic instead of the monophasic response (as we must do in human muscles), the maximum e.m.f. will depend on the degree of interference between the two phases—i.e., on the interval separating the moments of arrival of the active region or regions at the two electrodes, and if we are dealing with a series of responses the interference of successive phases will still further complicate matters. All this would be true of a muscle stimulated artificially, so that all the fibres are activated together; a much greater source of uncertainty arises from the fact that in a centrally innervated contraction various groups of fibres may be contracting independently of one another. Clearly the response in the galvanometer could be reduced to nothing at all if there were two groups of muscle-fibres activated alternately so that the action current due to the one group is always in the opposite direction to that in the other group, and generally the less perfect the synchronisation of the different fibres, the smaller will be the average effect at any moment as shown in the string galvanometer. It is in cases of this kind that needles in the muscle have the advantage over pads on the skin, for the latter record the average current in the whole muscle, but with needle electrodes the fibres in the straight line between them will have a greater effect on the galvanometer circuit than the fibres in outlying parts of the muscle. For a further discussion of some of these points we may refer to a recent paper by Forbes and Cattell[15] on the crossed extension reflex.

FIG. 3.



Oscillating action currents from thigh extensors of a cat during decerebrate rigidity.

There is one outstanding case in which a centrally-innervated contraction shows no electric response at all in spite of sensitive recording and rigid technique. This is the case, described by Magnus and Lilliestrand,[16] of the sustained reflex contraction brought about by the injection of tetanus toxin into a muscle. In patients suffering from the disease the contracted muscles have been found by some observers to give the oscillating response and by others to be current-free. In Magnus and Lilliestrand's experiments, however, there seems no doubt of the absence of response in the galvanometer. The contractions were certainly reflex in origin and they were not affected by section of the sympathetic. Whether the absence of response is due to complete lack of synchronisation in the different fibres is a question which must be settled by further investigation.

The conclusion to be drawn is, therefore, that the small size of the electrical effect in certain types of contraction is no proof that these contractions are a mixture of a tetanus and a steady activation which has no electric response. They do not show that a steady effect does not exist, but with the one exception mentioned, the main result is that all kinds of contractions, centrally innervated, are partly at least of a tetanic character.

Lewy has recently brought forward some evidence that in contractions with a marked "tonic" element there is another kind of electric response which shows itself by a steady deflection of the string.[17] If it were proved that a steady current does flow through the muscle when it contracts, it would be valuable evidence for the dual nature of the contraction, but great caution is needed in the interpretation of such effects, as the steady current may be due to changes in the electrodes and galvanometer circuit as well as to changes in the muscle. Einthoven[18] has shown that in decerebrate rigidity there is often a displacement of the mean position of the string and a return to the undeflected position when the contraction is inhibited. But he found that exactly the same displacement is produced by a passive movement of the muscle and concluded that it is due to the alteration in the resistance occurring when the electrodes are moved nearer to one another. Again, Stanley Cobb has published some records of electromyograms[19] which show steady deflections quite indistinguishable from those of Lewy, but Cobb is clear that the movement in his records is due to imperfect fixation of the electrodes on the skin. No doubt these sources of error were taken into account, but their possibility makes one hesitate to accept Lewy's conclusions without further confirmation.

It may be mentioned here that the time-relations of the contraction are much slower in red muscle than in white, so that a red muscle-fibre should be able to give a sustained contraction with a much smaller energy expenditure than a white. But the contractions are of essentially the same type in the two and the electric response of red muscle has the usual form, though it is slower in development and decline.

We must be content, then, to leave undecided the question whether the nervous system produces any sustained contractions which take place without the usual oscillating action current and to return to the consideration of the oscillations themselves.

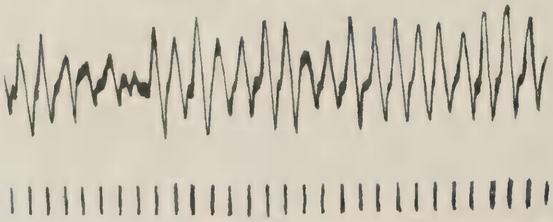
Now, whatever may be the reason for the characteristic frequency and shape of the electromyogram curves, there is no doubt that the oscillations are a sign that the muscle is actively contracting. Thus, without further interpretation, the electromyogram may be used to indicate the onset of activity in different muscles, and in several respects it is a more convenient index than the other signs of activity which may be recorded—the contraction, the mechanical vibrations, or the muscle sound. It has been used in this way for the analysis of movements by Golla and Hettwer,[20] and by Wachholder.[21] The problem which confronts us to-day, however, is to see if we cannot make use of the electromyogram to tell us more about the nature of the activity in the muscle and about the processes in the central nervous system which make it active.

FREQUENCY OF OSCILLATIONS.

For the reasons which have been mentioned, we can get little definite information by measuring the amplitude of the movements of the string—in other words, the strength of the currents in the galvanometer circuit. The frequency of the oscillations should have a much greater significance, and most of the investigations of the electromyogram have centred round this point. It would probably have been a great deal easier to analyse the processes at work if the frequency had shown great variations under different conditions, but we must take nature as we find it, and one of the chief features of the electromyogram is the close family likeness of all electrical records of voluntary contraction. The oscillations are usually irregular and the total number in a second may vary over a fairly wide range, yet the range of variation is much the same for every muscle and for every kind of contraction, so that it would be impossible from an inspection of an actual record to say anything more than that it was a normal electromyogram. A considerable change in the force of contraction does not produce a definite change in the frequency of the oscillations, but merely one of amplitude, and, indeed, the only "normal" condition where the frequency does change is in extreme fatigue, where it is temporarily reduced.

It would not be true to say that the oscillations are completely irregular, though there are often long stretches in a record where the waves seem to occur at random within the limits imposed by a frequency of 50–250 a second and where the most painstaking Fourier analysis seems unlikely to split up the record into trains of regular waves at different frequencies. It is a curious fact, however, that Piper, who was the first to make any detailed investigation of the electromyogram, was satisfied that there was always a dominant frequency in the record of about 50 a second. According to him the typical response consists of a series of large waves occurring regularly at a frequency of about 50 a second with a variable number of smaller waves superadded. His records bear out this statement, but many other workers have been unable to detect any sign of the dominant rhythm. Three years ago my respect for Piper's rhythm was considerably increased by obtaining a record in which the rhythm was remarkably steady (Fig. 4). The record was from the deltoid of a patient with dystrophia myotonica, and for this reason it cannot be described as a normal electromyogram, but since then I have been under the impression that something approaching Piper's rhythm can be found in records of very powerful contractions, though a weaker contraction is less likely to show it. This impression, for which I had very little evidence, has been confirmed by the work of Henriques and Lindhard,[22] which shows very great regularity in the electromyogram of maximal voluntary contractions, but little or none with weaker movements. The frequency of these regular oscillations varies in their experience from about 40 to 65 a second and may vary from one muscle to another in the same individual. A long record will often show small patches of fairly regular waves broken up by irregular waves at a higher frequency (Figs. 5, 6, and 7). It is doubtful if the records are ever completely regular, for measurements of the intervals between the peaks of successive waves will generally show slight variations, but in a "regular" record all the intervals are grouped fairly closely round the average value.

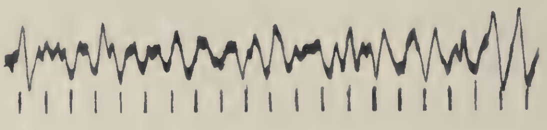
Fig. 4.



Record from deltoid of a case of dystrophia myotonica, showing regular waves.

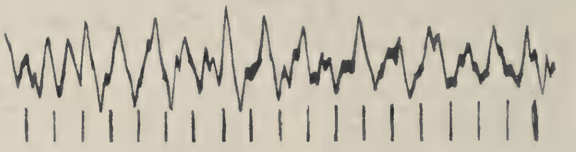
The maximum frequency is not easily determined, for it is certainly high enough to be near the limits of capacity of the ordinary string galvanometer. Using the very perfect instrument at the Marey Institute, Athanasiu[23] has obtained electromyograms with small groups of waves occurring at frequencies as high as 400 to 500 a second. Except in extreme fatigue or in certain experimental or pathological conditions, the frequency is seldom less than 50 a second. Recently, however, Wachholder[24] has detected a series of small waves at very low frequencies (five to ten a second) in all muscles which are not completely relaxed. The waves are diphasic and are recorded with needle electrodes and a tight string. This observation, if generally confirmed, would have an important bearing on the problem of tone and the postural reflexes in general.

Fig. 5.



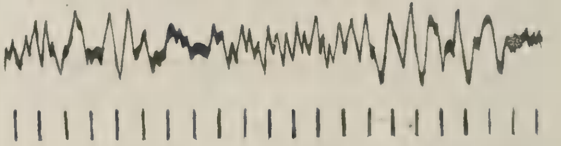
Powerful contraction of supinator longus.

Fig. 6.



Powerful contraction of biceps.

Fig. 7.



Weaker contraction of biceps. Waves more irregular.

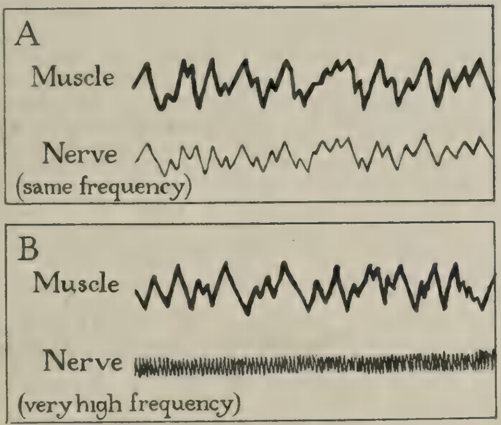
Changes in Frequency.

Apart from the tendency of the oscillations to become more regular when the strength of contraction is maximal, there is no significant change in the normal muscle except in extreme fatigue. Nor has any characteristic frequency been detected in the involuntary movements of various nervous diseases. An exception ought, perhaps, to be made in the case of ankle or patellar clonus, for here each movement is accompanied by a single diphasic action current and not by a series. There are some indications of a reduction in frequency when the sensory nerves from the muscle are interfered with. Weizsäcker[25] has reported a case of this kind with a lesion of the posterior roots and an electromyogram showing waves at only 19 a second, and Dusser de Barenne[26] has reduced the frequency of the oscillations led off from his forearm muscles by injecting novocaine into them in a dose sufficient to anæsthetise the sensory but not the motor nerves. Another way of reducing the frequency is by cooling the muscle. This effect was discovered by Forbes and Rappleye[27] and by Fahrenkamp,[28] and it is sufficiently obvious to be used as a class demonstration. The exact relation between the temperature of the muscle and the frequency of the electromyogram remains to be worked out, but my impression is that a considerable fall of temperature is needed to produce any change in frequency. This completes the list of conditions where the rhythm undergoes a definite change—i.e., a change outside the limits of the ordinary variations of frequency.

THE MEANING OF THE NORMAL FREQUENCY.

What deductions can be drawn from the normal electromyogram, what does it tell us about the nature of the voluntary contraction, the state of the muscle, and the activity of the motor neurones? So far the only conclusion reached has been that the voluntary contraction is tetanic, the muscle, or that part of it which furnishes the electromyogram, being activated intermittently and not continuously. What we have still to discuss is the rate at which this activation takes place, and the question is really of fundamental importance. The point is that a record like the typical electromyogram might be obtained by stimulating the motor nerve to the muscle at a very high frequency (500–1000 a second), which is too rapid for the muscle to follow (Fig. 8). If the voluntary contraction is maintained by a discharge of impulses at such high frequencies from the motor centres, the frequency recorded in the electromyogram represents merely the best that the muscle can do. It will be determined by the state of the muscle, the length of its refractory period in particular, and it will tell us nothing about the activity of the nerve centres except the one fact that they discharge at a frequency too high for the muscle to follow. This possibility may be considered as at one end of the scale. At the other we have the possibility that each wave in the electromyogram is determined by a distinct volley of impulses from the motor centre. According to this interpretation, therefore, the record can give us fairly detailed information about what is happening in the spinal cord. According to the other it can tell us little or nothing.

FIG. 8.



The truth probably lies somewhere between these two extremes, for it is unlikely that the motor neurones discharge such a rapid and steady flow of impulses that the electromyogram bears no impress of what is happening in the cord, and on the other hand, the interpretation must always be complicated by the fact that the fibres of the muscle are not all necessarily acting in unison. On the whole, however, the balance of evidence is in favour of the view that the frequency in nerve-fibre and muscle-fibre is the same, or at any rate, that the two are closely related. This evidence will be discussed in the next lecture.

TUBERCULOSIS IN THE TROPICS.*

BY SIR JAMES K. FOWLER, K.C.V.O., C.M.G.,
M.D., D.Sc. (HON.),

MEMBER OF THE COLONIAL ADVISORY MEDICAL AND SANITARY
COMMITTEE; CHAIRMAN OF THE COLONIAL MEDICAL
APPOINTMENTS SUBCOMMITTEE; CONSULTING
PHYSICIAN TO THE BROMPTON HOSPITAL
FOR CONSUMPTION AND DISEASES
OF THE CHEST.

JUDGING from the annual medical reports of the British colonies, I fear that we must conclude that pulmonary tuberculosis is on the increase amongst the native inhabitants of most of them. Tuberculosis may not loom very largely in the curricula of schools of tropical medicine, but diseases refuse to be localised and assert their right to world-wide prevalence and to this law it is no exception. The features of tuberculosis as it occurs in the tropics are, I think, more concerned with the inhabitants, with their past history in relation to it, and with their housing and mode of life, than with the climatic conditions which are peculiar to tropical countries. The evidence is overwhelming that when tuberculosis is introduced into a country hitherto free from it, the natives manifest a degree of resisting power much inferior to that shown by inhabitants of countries in which it has been present for countless generations. It may be well to consider for a moment the reason for this difference, as much appears to depend upon the explanation which is accepted. Possibly an analogy may help towards a solution of the problem.

In 1910 I was appointed chairman of the Yellow Fever Commission (West Africa). This work led me to take a special interest in that disease and to ponder over the assumed immunity of the natives. I was gradually led to see that no such absolute immunity exists, and that to speak of the natives as the "immunes" and of the Europeans as the "non-immunes," as was then and still is the practice, was to ignore obvious facts. There have been fatal cases amongst the natives in every epidemic in West Africa, not only in the past, but also in recent times. The mortality-rate amongst them as compared with that obtaining amongst the Europeans is no doubt nearly always much lower and the type of the disease is, as a rule, milder, but they are not immune. Why is this? The answer given by Sir Rubert Boyce was as follows:—

> "Those living in a country where the disease is endemic at a very early period in their life get an attack of the disease which naturally confers a certain degree of immunity; later they may get subsequent attacks, but each successive attack is less serious; when manhood is reached the subject is in all probability completely immune."[1]

The investigators sent out to West Africa by the Yellow Fever Commission, all of them carefully selected men, were specially instructed to search for evidence of the occurrence amongst the natives of attacks of fever which conformed to Sir Rubert Boyce's views, but no such evidence was obtained. It must, however, be admitted that it is a very difficult matter in West Africa to obtain trustworthy evidence as to the nature and incidence of the diseases which affect the natives.

---

* A paper read at the International Conference on Health Problems in Tropical America, held at Kingston, Jamaica.

[1] Brit. Med. Jour., Dec. 3rd, 1910.

I believe that in one form or another the view of Sir Rubert Boyce is still held, but I have great difficulty in accepting it. There is probably no disease an attack of which produces a more profound and lasting immunising effect upon the subject of it than yellow fever, so rare indeed is a second attack that many deny its occurrence. Must we, notwithstanding this fact, believe that every native has four or five such attacks during his life and requires them all to produce such a relative insusceptibility as we admit him to possess? But this is not the only difficulty. If there are at all times sufficient infected stegomyia in West Africa to ensure that all the natives in childhood, youth, and adult life receive doses of the virus adequate to confer upon them their relative degree of insusceptibility to yellow fever, why do Europeans escape for such long periods that the memory of the last epidemic is often lost and replaced by a hope that the disease has at last disappeared from among them? Is this, then, the only way in which a native race can obtain an immunity, either complete or partial to a disease, or failing that, a higher degree of resisting power than the "new-comer" to the country? Yellow fever is pre-eminently a "new-comer's disease"; so also, I submit, is tuberculosis. In the case of yellow fever, the white man usually goes to the disease from a country or an area in which it is unknown; he has little or no acquired resisting power and is fortunate, should he be attacked, if he escapes with his life.

In communities hitherto free from tuberculosis it may first appear, or be more marked, amongst outlying sections of the people in contact with long infected nations, or the native may himself introduce it on his return from such an infected country, whither he had gone either to work or to fight. However it may reach him he is found with little or no resisting power, and if attacked his chances of recovery, or, apart from that, of maintaining a prolonged fight with the disease, are inferior to that of the man who has lived amongst it all his life.

You are all familiar with the figures showing a gradual increase in the percentage of positive results with the subcutaneous tuberculin test and with other tests which indicate that as age advances the percentage increases until in adult life all, or nearly all, give a positive reaction. It has been stated thus: "Children not born of mothers in an advanced stage of tuberculosis come into the world in most cases free from tuberculous infection. As each year advances a progressive number become infected until at the age of puberty a total of one-half is reached. By the time he is adult practically every individual is the bearer of a tuberculous lesion."

If we accept this view, are we to base our methods of dealing with the disease and our treatment of the individual patient upon the conclusions to which it inevitably points? This is not a merely academic question, it is one of vital importance to the clinician, as the following extracts show: "Meanwhile let us lose no time, but take all possible advantage of the scientific facts already established. Let these serve as a basis for concerted action in anti-tuberculous prophylaxis. Since every human being under present social conditions is exposed from an early age to bacillary infection, it is most necessary that children be kept under strict supervision, so that by means, for example, of tuberculin tests repeated every six months any recent contamination can be detected and its source determined."

Here again is the same view stated with equally absolute precision: "The future of tuberculosis prevention lies in the deliberate exploitation by immunisation by means of vaccinating doses of dead or attenuated bacilli." Is this the best way and the only way to obtain an A1 population? I think that before we can accept it we must know clearly the meaning of a positive reaction to these tests and also the significance of a "focal" reaction. Does a positive reaction imply that the disease is present or does it merely indicate that at some time in the life of the individual he has been infected with tubercle? A disease and the virus of a disease are not the same thing.

Colonel Bushnell, in a Study in the Epidemiology of Tuberculosis with special reference to Tuberculosis in the Tropics, writes as follows: "The cutaneous tuberculin test is of value in diagnosis if the result is a positive reaction. It is, however, likely to be negative in the class of cases which most require elucidation." It cannot be claimed that this is very helpful. He quotes Mirauer's [2] results of the examination of 145 non-tuberculous patients, of whom 128, or 88 per cent., gave a positive reaction, and also of 53 tuberculous suspects, of whom 46, or 87 per cent., also gave with 100 per cent. tuberculin a positive reaction. The positive percentages with 25 per cent. tuberculin were 79 and 77 respectively. In discussing Bandelier's [3] results in the examination of 500 sanatorium patients, Colonel Bushnell wisely remarks: "Whether all patients who react in so slight a degree are in need of sanatorium treatment is a question that might be raised by the critical." As one of the critical I venture to exercise that privilege.

Dr. Noel Bardswell, who has had an exceptional experience of this disease, in a paper on the Subcutaneous Tuberculin Test,[4] writes as follows:—

> "Failure to react to tuberculin does not exclude tuberculous disease."
>
> "In my opinion the test is not a means whereby the existence or absence of tuberculous disease can be determined. Neither when a tuberculous lesion is present does the test give any information as to its activity. Lawrason Brown and Heise have arrived at substantially the same conclusions." [5]

A "focal" reaction is, however, quite another matter; here there is a lesion the presence of which, if it is in the lung, can possibly be determined by physical or X ray examination. In a work on "Pulmonary Tuberculosis" (p. 260) I described the effect of tuberculin on a man of high resisting power and with the form of the disease which goes with such a high resisting power—i.e., fibroid tuberculosis—and what was the result? Four calcareous particles were expectorated, one surrounded by pigmented lung tissue; another portion of lung tissue; and one cavity was formed. It is usually wise not to disturb sleeping dogs. On p. 55 of the same work I mentioned the case of a man whose life for 40 years had hung upon the precarious integrity of a fibrous capsule around a caseous mass, and who, when the capsule gave way, was dead in 28 days from acute miliary tuberculosis of the lungs. Now combine these two cases and give the second man sufficient tuberculin to produce a "focal" reaction. What might and what almost certainly would have been the result? He would have been dead in a month. Focal reactions in cases of pulmonary tuberculosis are, in my opinion, not free from risk.

The almost universal prevalence of tuberculosis after a certain age has been reached is held to be further confirmed by post-mortem statistics, those of Naegeli being most often cited. It is obvious that without some measure of agreement as to what is to be accepted as a tuberculous lesion the figures of different observers dealing with different nations are likely to show a wide divergence. If a pleural adhesion is regarded as of equal value to a puckered cicatrix near the apex of the lung, with a pigmented fibro-caseous or calcareous nodule about its centre and compensatory emphysematous changes around it, then of two observers one may absolutely reject the former lesion—i.e., the pleural adhesion—as trustworthy evidence, whereas both would accept the latter. Yet I have heard it contended that a pleural adhesion is evidence of previous tuberculous infection. I have observed that the only subjects above middle age who are or may be entirely free from pleural adhesions are the subjects of general emphysema. In such cases on autopsy the lungs may come out of the thorax as readily as they do in the case of a child. How is this to be explained? For many years I made many post-mortems and evidence of arrest of tuberculosis was always sought for, but I was not "out" to find few or many such obsolete lesions, but to prove that they were tuberculous lesions. It is a dangerous thing to be on the look-out for evidence in support of a theory; if so, one is very likely to find it.

[4] Tubercle, July, 1921, p. 433.

[5] Twenty-four Years' Experience with the Subcutaneous Tuberculin Test, Amer. Jour. Tuberc., June, 1920, iv., No. 4.

Some years ago my friend Sir John Rose Bradford, F.R.S., who during the whole of the war was consulting physician at the Etaples Base, when preparing the Lumleian lectures[6] (1920) on the Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914–1919, asked me in what percentage of post-mortem examinations I should expect to find obsolete tuberculous lesions; my reply was, "In about 9 per cent." He said, "I thought you would say 90 per cent. It is curious that that is the exact figure obtained from an analysis of 2121 post-mortems at Etaples." The figures are as given in Table I.

TABLE I.—*Etaples Area, 1917–18.*

	No. of cases.
1. Post-mortem examinations	2121
2. Tuberculous lesions were found in	256
3. Death in these 256 cases was directly due to tubercle in	62
4. The total incidence of tuberculous lesions in the whole of the post-mortems made was 12 per cent.	
5. Obsolete tuberculous lesions were found in men dying from wounds or some other accidental cause other than tuberculosis in 9 per cent. of the total number examined.	

These figures are to me very interesting. Here we have a striking confirmation from an absolutely independent and trustworthy source of the accuracy of the figures of myself and Dr. Sidney Martin, F.R.S., published in 1891, which have hitherto been considered to be far too low. By assembling the three independent observations we get Table II.

TABLE II.

Date.	Source of material.	No. of post-mortems.	Obsolete tuberculous lesions in lungs.
1879–86	Middlesex Hosp. (Fowler).	1943	177 (9·0 %)
1890–91	Middlesex Hosp. (Martin).	445	42 (9·4 %)
1917–18	British soldiers in France (Etaples) (Bradford).	2121	191 (9·0 %)

The incidence of and mortality from tuberculosis among the native and British troops in France in 1918 is shown in Table III.[7]

TABLE III.

—	Annual case incidence per 10,000 of annual average strength.	Annual deaths per 10,000 of annual average strength.
South African Native Corps .	186	167
Cape Coloured Labour Corps.	444	88
Indian Native ,, ,, .	142	53
Chinese ,, ,, ,, .	36	12
British troops in France and Belgium	10	0·5

It is interesting to note that no obsolete tuberculous lesions were found on autopsy of the native troops; evidence of a lack of resisting power. We are all agreed that racial and family characters of body and mind, endless in number and variety, may be transmitted from one generation to another through countless ages from father or mother to son or daughter. The laws governing such inheritance are being slowly but surely worked out.

I account for the greater resisting power of the natives of certain countries to yellow fever or to tuberculosis by assuming that if all the minute details above referred to can be contained within their chromosomes, so also can a greater or lesser resisting power to disease, acquired by the contact of countless generations with that disease, be there and be transmitted. One individual may have high or low resisting power to disease in general, whereas another may have a high or low resisting power to a special disease, and such special liability may be evidenced by certain characters of the body and of the mind. The reason why it can be said that "Mary Jane brings all the catching diseases into our family" is that Mary Jane has a low resisting power to disease in general, but she may be quite free from any special liability to, say, tuberculosis, notwithstanding the fact that one of her sisters presents all the features characteristic of that liability. It is the modern fashion either to deny the existence of such indications or to minimise their importance. I am not suggesting that the disease itself is transmitted, as I have for years taught that in the case of private patients, that is of those whose former history can be most closely investigated, if it is thought to be worth the trouble, in the majority of such cases it is possible to arrive at a fairly accurate opinion as to how, when, and where infection occurred.

Tuberculosis, and especially pulmonary tuberculosis, is a disease the clinical course of which presents such wide variations and leads to such startling and unexpected terminations, either in death or recovery, that it requires almost a life-time to obtain such a knowledge of it as enables one to speak with even a semblance of authority. Amongst those physicians who have had this experience I have found but little divergence of view as to the existence of individuals of the type just referred to, nor have they any doubt that in England it is a type which is now steadily diminishing in numbers, but as between them and those who have not had this experience there is a wide divergence of view. Some families, Nature's masterpieces—survivals like Old Masters and the Classics from much rubbish—are endowed with such a high degree of resisting power that they persist through many successive centuries without manifesting any inherited tendency to disease. I am acquainted with a member of such a family from whom I learned that his ancestry has now been traced to three generations prior to 1300, and that in the elder branch of the family the succession from father to son has been unbroken through all those years. In this family to-day they think nothing of 80 years, and only begin to feel old at 90; about 96 they may die, apparently out of consideration for the claims of the rising generation.

I see no necessity to assume that Nature restricts herself to one method only in arming her most finished product against the microbial millions also of her fashioning, which to us are diseases, but which to themselves are species that must be maintained. I do not believe in the deliberate exploitation of immunisation by means of vaccinating doses of dead or attenuated tubercle bacilli as a method of creating an A1 population. I would rather strive in every possible way to improve the physique of the nation and thus to increase the resisting power of the people to disease, including tuberculosis. The fall in the death-rate from pulmonary tuberculosis in Great Britain began before modern sanitary measures had had time to operate, and it will be accelerated in that and other countries when governments appreciate to the full that the provision of healthy homes for the people is a matter far transcending in importance any other with which they are called upon to deal.

[6] THE LANCET, 1920, ii., 539.

[7] The Primitive Tribes and Tuberculosis, S. E. Cummins, Trans. Soc. Trop. Med., June, 1912, v., No. 7, 245.

Administrative Measures.—Notification.

I now pass on to consider administrative measures for dealing with tuberculosis in the tropics. If one is attempting to estimate the result of a method of preventing or treating a given disease it is obviously essential to ensure that the cases dealt with are really examples of that disease. In a booklet entitled "Problems in Tuberculosis," recently published (1922), I have given the evidence on which is based the statement that during the war 75 per cent. of the diagnoses of pulmonary tuberculosis in regard to the British troops were erroneous. Dr. Rist, of Paris, an authority on the subject, has confirmed my statement by citing similar facts in regard to the French troops, and in other countries the same error was made in a like proportion.

Whether notification of tuberculosis should be enforced must depend in the tropics upon the local conditions and upon the degree of civilisation to which the people concerned have attained. It is useless if the notifications, as is too often the case, are only received a short time before the death of the patient or after his decease.

The value of notification, apart from statistical inquiries, depends upon the use that is made of it in dealing with contacts and in removing them from unhealthy surroundings.

After-care committees and local tuberculosis centres are valuable adjuncts in any administrative scheme. The latter name avoids the use of the word "dispensary," which in Great Britain is regarded as a place where drugs are to be obtained.

Specific Remedies.

I have never met with a case of pulmonary tuberculosis in which I have been able to satisfy myself that any good had resulted from the administration of tuberculin, but I have seen many in which any chance of recovery that the patient possessed had been destroyed by its use. The time has been too short for a reasoned judgment on the value of Prof. Dreyer's diaplyte vaccine, but, speaking generally, opinion is not favourable. I have seen a case treated with it in which 1/200,000 of a milligramme induced a reaction followed by eight days of continuous fever, whereas previously the temperature had been for a considerable period hardly above normal. Like other forms of tuberculin, it is probably a measure of the resisting power of the individual. Before any clinical use is made of such a remedy or of anything of a similar nature which may be brought forward in the future, it is necessary that overwhelming evidence should first be produced that it confers immunity on animals. This appeared to me to be the weak point with regard to Prof. Dreyer's diaplyte, and subsequent investigations have shown that it does not produce any such result. The 1923 report of the governing body of the Lister Institute, of which I am a member, contains the following statement:—

> "Dr. Schütze has in the past nine months tested the therapeutic value of Dreyer's diaplyte vaccine on tuberculous guinea-pigs. No evidence whatever has been obtained that the course of the disease in these animals is favourably modified by this treatment."

Sanatoria.

In temperate climes sanatoria at high altitudes present an undoubted advantage. In the tropics the conditions at such altitudes, if they are available, may or may not be suitable to a native population. The sanatorium should be situated on the healthiest site available and should be the nucleus of a settlement, as at Papworth Hall in Cambridgeshire. The other features of such a settlement appear in the following

Scheme for a Tuberculosis Settlement.

Sanatorium Department.—Diagnosis ward; clinical ward; operating theatre: visiting surgeon; X ray installation; clinical laboratory; sanatorium block; graduated exercise and graduated labour.

Hospital Department.—Hospital block.

Industries Department.—Huts; hostels; cottages; workshops: (*a*) training, (*b*) handicrafts; outdoor industries; sale of produce.

(*a*) *Diagnosis Ward.*—All patients on admission should pass through this ward, remaining there until the fact that they are really cases of pulmonary tuberculosis has been settled. On leaving this ward patients would be transferred to the sanatorium block.

(*b*) *Clinical Ward.*—This ward should be occupied by cases requiring close observation and those in the earlier period following the operation of artificial pneumothorax; which will in future play an increasing rôle in the treatment of the disease amongst the industrial classes.

(*c*) *Operating Theatre and X Ray Installation.*—These are essential, if artificial pneumothorax and the use of the thoracoscope form part of the treatment adopted.

(*d*) *Sanatorium Block.*—For patients going through the usual sanatorium course, but in whom arrest of the disease has not yet been obtained.

Hospital.—For advanced cases and such as do not respond to sanatorium treatment or who break down when engaged in the industries.

Huts and Hostels.—When the patient leaves the sanatorium and has been through his course of training it is no longer necessary for him to occupy a bed in an expensively equipped ward, and it costs much less to maintain a considerable number of two-bedded open-air huts. To be transferred from a hut to a hostel is a step in promotion; and a definite flow of promotion is one of the secrets of the successful working of a settlement.

Cottages.—For married men; a further step in promotion.

Workshops.—Training in industries carried on in hygienic workshops involves in temperate climes less exposure to climatic conditions, which may be harmful, than open-air occupations, but in the tropics such considerations may not apply.

A settlement, unlike a colony within a ring fence, forms part of the community as a whole. Main roads may pass through it. Its shops are open to all. Its industries employ such of the tuberculous as are capable of work, and many of them are so; their wages help to maintain themselves or their families; their work, if properly controlled, contributes to their health and promotes their happiness; the products of their labour are sold in the open market, and they are paid the wages customary in their particular industry, having regard to restricted hours of labour and to an output less than that of a healthy man.

The open secrets of the successful management of the industries of a settlement are: (1) All heads of departments must be men who have themselves gone through the tuberculosis mill. (2) There must be a prospect of promotion for all. (3) Repetition work which can be easily learned is the chief feature of the industries, whereas a new handicraft can only be acquired by long application. (4) All the heavy work must be done by machinery. (5) Every department must be run on business lines; a settlement is no place for amateurs. (6) The ideal head of a settlement is a physician with a flare for organisation and business.

The sanatorium is no longer the unit, it has become merged in the settlement.

That such a tuberculosis settlement is not a plague-spot, avoided by its neighbours, is shown by the following extracts from a letter from Dr. P. C. Varrier-Jones, the director of Papworth industries, and from many visits I am able to confirm his statements:—

> "We have experienced no local objection whatever. Indeed, our village is so much more prosperous than those in the surrounding country that our inhabitants are, I hear, looked upon with green-eyed jealousy. Wages are better than in the villages, and the conditions superior, so that instead of opposition we have readiness to coöperate in trade and other ways."

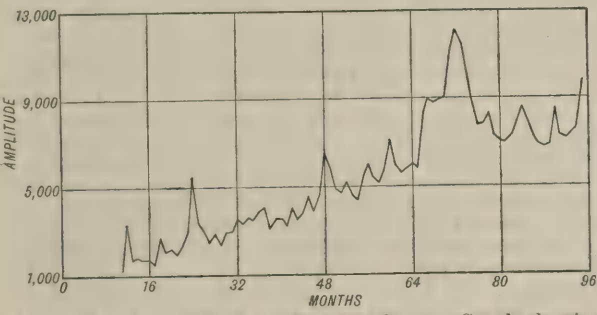
My advice to any colony disposed to grapple seriously with the tuberculosis problem is to destroy its slums and to start a tuberculosis settlement on the lines which I have herein suggested. Any country that rejects compulsory vaccination and retains its slums must pay for small-pox hospitals and tuberculosis settlements. The tuberculosis problem is to a very large extent a housing problem in all parts of the world.

"PERIODICITY" OF CHOLERA IN INDIA.

BY A. J. H. RUSSELL, C.B.E., M.D. ST. AND.,
MAJOR, I.M.S.; DIRECTOR OF PUBLIC HEALTH, MADRAS PRESIDENCY.

RECENT bulletins issued by the Health Section of the League of Nations show that at the present time India is practically the only part of the world in which cholera exists in epidemic form. India has, of course, been long recognised as one of the important centres for this disease, although it is doubtful if Bengal is the only "endemic home" of cholera in India as has so often been stated. But very little information of value has been recorded in connexion with its epidemiological features.

There can be no question that cholera has in India a regular seasonal periodicity. This feature of the disease has been indeed recognised wherever cholera has been experienced. Examination of the statistics for cholera deaths in the Madras Presidency over a long period of years showed that the annual periodicity occurred with the greatest regularity. When graphs were prepared by plotting the monthly number of deaths over this prolonged period this annual periodicity was not only demonstrated, but a longer periodicity wave became fairly obvious. J. Brownlee, the statistician with the Medical Research Council, has demonstrated the 87-week and 97-week periodicity in measles epidemics in a number of towns in England by a method known as the periodiogram analysis. This method has been applied to the cholera deaths for Madras Presidency for a peiod of 25 years, the statistics being arranged in three groups of districts, according to the periods in which these districts were affected by the different monsoons. In each of the three groups the annual periodicities are very apparent; but by far the highest amplitude is reached in each group at the 72-month period, which proves that cholera in Madras Presidency, for the period o years under examination, has gone through a regular six-yearly cycle. As far as the writer has been able to discover, no such periodic trend has previously been demonstrated in connexion with this disease, and the first question which naturally arises is whether the same periodicity holds good for other provinces or other endemic centres in India, or whether the harmonic curve is a mere chance occurrence. From work done during the last two months the writer is now in a position to state that the same six-yearly periodicity has occurred in Bombay Presidency, the Punjab, the United Provinces, the Central Provinces, and in Mysore over the period 1896–1923.



Madras Presidency, Northern Districts Group: Graph showing monthly amplitudes over period 1902–21.

This fact seems to be of sufficient importance to have it recorded at the earliest possible date. Further work on the same lines is being carried out; but even if the conclusions arrived at hold good only for those enormous areas—which include the greater part of the Indian continent—it is a fact of far-reaching importance in connexion with the measures usually utilised for prevention of the disease. No mention has been made of the so-called "endemic homes" of cholera—viz., Bengal and Assam. The statistics for these provinces will be analysed later and the results published in a further communication, along with other work on the same subject. Meantime the mere knowledge of this six-yearly periodicity has enabled the public health department in Madras Presidency to control its preventive work in connexion with the disease, and has prevented waste of effort in unnecessary directions at unnecessary times. The graph shows the monthly amplitudes for one of the three groups of districts in Madras Presidency. The annual periodicities are quite obvious, but the most striking feature is the enormously high amplitude at the 72-month period. It is typical of the graphs obtained for the other two groups of districts in Madras Presidency, and also for those of the other five provinces mentioned above. Full details of the statistical work done and further points in connexion with the epidemiology of cholera will be published separately.

Clinical and Laboratory Notes.

A CASE OF HÆMOPHILIA.

BY W. B. BURKE, L.R.C.P. & S. IREL.,
HON. SURGEON, VICTORIA HOSPITAL, WORKSOP.

THE following case is interesting owing to the unusual position of the hæmorrhage, and the apparently unknown cause.

L. S., male, aged 18, was admitted to the hospital on August 12th, 1924, under my care. He was sent in as a possible case of psoas abscess.

On examination he was seen to have marked flexion at the right knee- and hip-joints with inability to move the limb at these joints; passive movement was very limited and caused great pain. The knee-joint was flexed to an angle of 45°. There was marked prominence of the right hypochondriac and right iliac regions, which on palpation suggested a large intra-abdominal tumour extending from the liver right down to Poupart's ligament. The whole area from the liver above to Poupart's ligament below and extending right over to the mid-line was dull. The skin over this area was normal. On examining the spine nothing abnormal was noticed and further physical examination elicited negative results. The boy was quite fit and doing his work up to three weeks before, when he first complained of stiffness in the right hip and numbness in the leg, as if the leg was "asleep"; he was then treated for neuritis. About three days before his admission he noticed a swelling in the right side which gradually increased.

Previous History.—At the age of 5 he had a tooth extracted and hæmorrhage of a severe character followed and continued at intervals for about two months. When 12 years old he had a further bad hæmorrhage following another extraction, after which he had to remain in hospital for five weeks. Two years later he sustained a blow on the leg which caused a large subcutaneous hæmatoma and necessitated his being in hospital for about two months.

Family History.—Of a family of four boys, one died in infancy of acute osteomyelitis of the femur, two others, still living, bleed extensively from the slightest trauma. One of these was under my care some months ago with a septic wound in the right forearm of a week's duration which had commenced to bleed violently. As none of the usual methods of hæmostasis acted successfully I tied the brachial artery, and in about seven days the pulse at the wrist was quite normal. The mother is healthy, but very anæmic in appearance; the father is healthy; the grandfather (maternal) usually bled on slight trauma and died from hæmorrhage following an accident in which his leg was badly injured. Remainder of family history on the mother's side unobtainable.

Operation.—On August 13th, 1924, the day following admission, the boy was given a general anæsthetic (C. and E.). I opened up immediately over the swelling, and on opening the anterior peritoneum I found a large tumour pushing forward the posterior peritoneum so that it was in contact with the anterior abdominal wall. The tumour had the appearance of a hæmatoma and filled up completely the right half of the abdomen. As I was unable to make a full exploration through the small original incision I temporarily closed the wound. A mid-line incision was then made and the abdominal cavity thoroughly explored. The organs were normal, the tumour being completely retro-peritoneal. Concluding that it was a hæmatoma I decided to evacuate it through my original incision so I reopened it, and having opened the posterior peritoneum cleared out two kidney trayfuls of blood-clots. This left a large cavity which seemed to end in a cul-de-sac about the lower pole of the right kidney which seemed normal, and there was no damage to any of the surrounding structures to cause the hæmorrhage. On removal of these clots the leg became straight, as the pressure was removed from the iliopsoas. The cavity was then plugged with gauze and the abdomen closed. There was no undue hæmorrhage at any time during the operation. Later in the day he was in a poor condition and had to be kept on rectal salines.

On the 15th the cavity was replugged. The patient complained of severe abdominal pain. The following day there was a good deal of hæmorrhage from both wounds and the dressings were soaked through. The wounds were dressed with gauze soaked with adrenalin solution, and hæmoplastin, 2 c.cm., was given. As the hæmorrhage continued I gave him 20 c.cm. of human blood intramuscularly into the buttock, and later in the day a blood transfusion—12 oz. of type 4. He was kept on hæmoplastin and horse serum for a few days and hæmorrhage gradually decreased until August 21st, when it ceased. I removed the stitches on that date and both wounds appeared healed. On August 23rd bleeding recommenced from the lower end of the mid-line incision and caused the wound to open up. Two sutures were inserted and collodion dressings applied, which stopped hæmorrhage except for slight oozing. He was now given 20 c.cm. of horse serum twice daily, but on the 25th a further blood transfusion of 1 pint was given, owing to his poor condition. This made a marked improvement, which was maintained until the 28th, when a large hæmatoma formed in the mid-line incision.

On the 29th, under general anæsthesia, I reopened the mid-line incision and cleared out several large clots which had formed between the peritoneum and the skin and not involving the abdominal cavity at all. I plugged the space with adrenalin gauze and put in a few retention sutures. For a few days after this there was some oozing, but the cavity granulated up from the bottom and healed. At a later date he was given a course of massage and electrical treatment to tone up the muscles of the leg. For a time the extensor action of the limb was somewhat weak, but at the present time this weakness has disappeared and the patient now walks normally and appears to be in good health.

Following the first operation the liver dullness disappeared completely and remained absent for about three weeks, an incident I am unable to account for. On each previous occasion, where trauma or surgical interference took place, I am told by his mother that no hæmorrhage occurred for three days, and it is interesting to note that the same period elapsed in this case.

I have not been able to determine what was the primary cause of the hæmorrhage as the boy denies having met with any injury even of a trivial nature, but it seems quite feasible that he must have sustained some crushing injury in the right lumbar region.

COAGULEN (CIBA) FOR HÆMOPTYSIS.

By ANDREW J. MORLAND, M.B., B.S. LOND.

IN the case here recorded arrest of severe hæmoptysis followed the intrapulmonary injection of coagulen (Ciba).

The patient, a strongly built male aged 33, entered the Palace Sanatorium at Montana on Feb. 14th, 1925. His tuberculous history began with a dry pleurisy on the right side in 1912. He appears to have recovered completely from this, as he served as an officer throughout the war, and was only in hospital for a few weeks after severe gassing in 1915. The patient began to cough towards the end of 1917, and tuberculosis of the right apex was diagnosed in 1918, the diagnosis being confirmed by the presence of T.B. in the sputum. Since 1918 sanatorium treatment has alternated with semi-invalid life at home. During the last year dyspnœa has been increasing, but in other respects the patient's condition has been practically stationary; he has been aware for some time that he had a large cavity at the right apex. The weight was 9 st. 7 lb., the highest known weight being 10 st. (in 1914).

On arrival the physical signs indicated the presence of a large cavity at the right apex; another cavity was suspected at the left apex, but X ray examination was typical of a localised pneumothorax just below the apex. The cavity at the right apex was seen to be surrounded by a dense fibrous wall. The patient complained chiefly of shortness of breath. For the first week or so the temperature (rectal) varied between 98·6° F. (morning) and 100° (evening). This gradually fell, and after four weeks of rest in bed did not exceed 98° in the morning or 99° in the evening. At this stage the patient was allowed to recline on a couch for an hour or two each day.

About a week later (on April 23rd) hæmoptysis of a pint took place between 10 and 11 P.M. The usual remedies were tried: absolute rest, injection of morphine, ice-bag, and tinct. of ergot. A hæmoptysis of 15 oz. followed between 4.30 and 5 A.M., and a further one of 23 oz. at 9 A.M. During this attack 5 c.cm. of coagulen (Ciba) were given by subcutaneous injection; the patient almost immediately began to experience unpleasant sensations described by him as a feeling of knobs appearing all over his body. The hæmorrhage gradually stopped about half an hour after the injection. At 1 P.M. the bleeding began again, about 12 oz. being lost in the first five minutes. At this time blood was welling up rapidly, about six mouthfuls being expectorated each minute; the patient had already, in about 15 hours, lost three and a half pints. Five c.cm. of coagulen (Ciba) were then injected directly into the cavity, over which bubbling râles were plainly audible. The spot chosen for the injection was the second intercostal space, about two inches from the margin of the sternum. The needle was inserted to a depth of about half an inch and the piston withdrawn, a mixture of air and blood immediately filling the syringe. The contents of the syringe were then injected; arrest of the hæmorrhage followed with dramatic suddenness, only one more mouthful of dark, partially clotted blood being expectorated. At 3 P.M., however, the bleeding began again; another injection of coagulen (10 c.cm.) was given in the same spot; the hæmorrhage stopped gradually about two minutes later, after a total loss of 10 oz.

During the following night there were two slight hæmorrhages of less than 5 oz., consisting mostly of clotted blood. Coagulen was not given. Recovery has been uneventful. The patient has regained his highest known weight (10 st.) and is able to walk two miles with ease.

Coagulen (Ciba), the substance used for injection, is prepared from the blood of animals. It consists chiefly of lipoids and is rich in thrombokinase. It has been used chiefly in surgery for the arrest of intractable hæmorrhage, as described by S. G. Papadopoulos in THE LANCET of Jan. 24th, but has also been given by subcutaneous and intravenous injection for cases of hæmoptysis. The intravenous method is more rapid and certain in its effects but tends to be associated with more or less severe shock. Intravascular clotting is said not to occur. The advantage of injection directly into the bleeding cavity is that the hæmostatic substance reaches the seat of the trouble in a high concentration while the unpleasant effects and possible dangers of intravenous injection are avoided.

Montana.

LEEDS: TRAINING HOSPITAL ALMONERS.—The Institute of Hospital Almoners has approved a scheme for training at the University of Leeds in coöperation with the Leeds Almoners' Training Committee, and grants towards the fees will be made by the Leeds Education Committee to candidates who are unable to meet the entire cost. The fee of the Institute of Hospital Almoners is 40 guineas and the training lasts for a minimum of two years. Hitherto London has been the only training centre, and it is obvious that the cost of residence there must deter many candidates from the provinces from qualifying for work of real importance to large hospitals.

WALKER ACCIDENT HOSPITAL.—This Newcastle-on-Tyne hospital dates from 1870, when it was established by the late Mr. Charles Mitchell, whose works were then the only ones in Walker. The recent transfer thither of the naval yard of Messrs. Armstrong, Whitworth and Co. has doubled the number of patients and additions and improvements had become imperative. These have now been made at a cost of £8000. Chief among the additions are an operating theatre and an X ray department, which, it is claimed, "cannot be excelled even by Newcastle Infirmary." This interesting little hospital has always been maintained by contributions from employers and weekly subscriptions from the operatives, who have agreed to double their contributions.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

A MEETING of this Section was held on June 3rd, Mr. HERBERT J. PATERSON, the President, being in the chair.

GASTRIC AND DUODENAL ULCER.

Dr. CHARLES H. MAYO (Rochester, U.S.A.) delivered an address on this subject. He said that in the development of surgery the first necessity had been to secure relief from suffering. Many years ago it was recognised that contractions of the pylorus caused inflammatory conditions around ulcers, resulting in obstruction, starvation, and slow death. Patients were ill for too long a time for the disease to have been cancer. Billroth, after carefully studying the sufferers, did a resection of the obstructed area at the site of the pylorus, partially closing the end of the stomach, and uniting it to the duodenum. In the early days of these operations the mortality was about 70 per cent. This high mortality was probably largely due to the fact that no special effort was made to protect the suture line, for the "suture angle," where there were three lines of stitches, was a frequent cause of trouble, and the duodenum was always a bad bowel to suture. Leakage resulted in most destructive digestion of the sutures. In his second type of operation, Billroth closed the end of the stomach and did a posterior gastro-enterostomy. Hartmann and Mikulicz made a new opening posteriorly, drew over the end of the duodenum, and sutured it in. The operation was not taken up extensively, however, nor was that of Hahn, who forced the stump through the end of the stomach and found the subsequent contraction was worse than before. Then followed the Ramstedt operation, dividing the pyloric muscle without opening the mucous membrane. This, said Dr. Mayo, was a sound proceeding and was still successfully done in the case of children with congenital contractions of the pylorus.

Suture Operations.

In 1892 Dr. John Finney, of Baltimore, devised and carried out the operation of suture of the pylorus and upper duodenum to the greater curvature of the stomach, then, through a horseshoe incision, forcing down the suture line, and closing the outer suture line over it. Dr. Finney had largely given up this operation during the last three years, substituting resection and division at the pylorus, making a new opening in the anterior wall of the duodenum, and suturing into it the pyloric end of the stomach. Dr. Mayo thought this operation was not likely to be very widely adopted.

Mechanical adjuncts, such as the Murphy button and the Mayo Robson bobbin, had a vogue, and the former was still used for specially suitable cases, but most surgeons decided that they did not need these aids. Senn, of Chicago, introduced and used decalcified ox-bone plates, and they were employed throughout the surgical world, but gradually the improved methods of suture took their place.

Next came the Polya operation, by which large areas of the stomach were excised, the end of the remaining portion being attached to the jejunum. This was of wide usefulness, and was being largely carried out to-day; but at times one encountered a very short mesentery in the attachment of the transverse colon, and then it was necessary to carry out the anterior operation of swinging the jejunum over the loop of the transverse colon and attaching it to the divided end of the stomach. The foregoing operations were devised mainly for the treatment of cases of cancer of the stomach, and it was remarkable how small a portion of stomach left to the patient after the operation would distend and usefully function. Balfour modified the Polya operation by working anteriorly, so avoiding an area where the rich blood-supply might cause the cancer to grow with such rapidity as to kill the patient by obstruction.

Gastro-Enterostomy.

Gastro-enterostomy had been quite a successful operation, and in process of time it became a safe and efficient one in the hands of many. Indeed, it seemed to have been performed by some without means being taken to ascertain whether the patient's complaints really had origin in an ulcer, for the symptoms could well be produced reflexly from, for example, gall-bladder trouble. Patients with any abdominal trouble were apt to locate it in the stomach. In one case a patient who had been operated upon elsewhere came to him and he reoperated and found the anastomosis had been made to the stomach within 9 inches of the lower ileum, in another within 10 inches, in a third within 18 inches. The greater part of the food was passing through the gastro-enterostomy opening. In two of the three cases mentioned he was unable to find any sign of ulcer of the stomach.

Very few people had a jejunum which passed straight down from its point of origin. Nearly always the first loop was the splenic loop on the left of the colon. In operating for gall-stones it was useful to remember there was a 50 per cent. chance that one would encounter the third loop, as the first and second were on the left side of the stomach. The third loop crossed the spine and sometimes caused a secondary obstruction ten days or so after the operation.

Discussion on the defects of gastro-enterostomy had led to the development, on the continent, of the great operation of excision of the stomach. He had seen cases in which only a small ulcer of the duodenum was present, giving rise to symptoms in the spring and fall of the year, and for this two-thirds of the stomach had been cut away to ensure freedom from those symptoms. Surgeons, he felt sure, would not consent to such a procedure in the case of their own stomach in order to rid them of trouble occurring beyond the stomach.

Occasionally a large ulcer would develop carcinoma in one wall as a result of chronic irritation. Small ulcers were seldom found to cause this degeneration. Usually these ulcers formed in the areas of highest acidity. In men one-third of the cancers were in the stomach, very few in the small gut. Balfour investigated the records of 1000 consecutive cases of ulcer of the stomach and duodenum which had been operated upon more than ten years before; and he found that 90 per cent. of them could be regarded as surgical successes. In the remaining 10 per cent. were included such troubles as hæmorrhage, obstruction, and gastro-jejunal ulcer. Four per cent. developed gastro-jejunal ulcer when silk was used for the ligatures, and since that had been abandoned the figure was reduced to 2 per cent.

Nature of the Ulcer.

These ulcers were held to be due to the action of acids and pepsin, and were frequently termed peptic ulcers. It was somewhat difficult to explain the occurrence of an ulcer in an acid-free stomach. In such a case one should not be content with a single test; a second or third should be carried out. The reason for this was that acid came strongly 80 minutes after a meal, continued for 20 minutes, and then disappeared. Histamine injections would bring back acid to a stomach from which it had been absent a considerable time. This procedure was not a treatment, but it showed something was wrong with a hormone. Subjects of achylia suffered from troubles in the nervous system. Some children with this deficiency had gastric convulsions and gastric tetany. Dr. Mayor considered that people who had achylia and ulcers for a long time had something wrong in the nervous system, and they were not likely to be greatly relieved. Inasmuch as these people had no acid or pepsin their ulcers were not likely to perforate. Patients with achylia had headache and other distressing conditions because of the alkalinity present.

Production of Ulcers.

Dr. Mayo said ulcers could be produced by large doses of drugs, also by bacteria. A dog, in experimental work, developed a reaction on receiving a chill and ulcers formed, but did not persist. But if the dog had chronic bacterial infection the ulcers continued. With regard to chemically produced ulcers, in most dogs a duodenal ulcer could be caused by separating the common from the pancreatic duct. If the lower duodenum were divided and united to the ileum, so short-circuiting the jejunum, there would be a large number of duodenal ulcers, and these would persist three weeks. Dr. John I. Hunter, a brilliant young anatomist, who recently died, showed that the sympathetic system used 75 per cent. of the total energy of the body; and he undertook an investigation on the proportion of muscles of the body which had only the power of fixation. On occasion these muscles went into a condition of spasm, and caused intestinal troubles. Sometimes cardiac spasm occurred and lasted years, and was cured by an over-stretching of those muscles. There might be present a particular spasm of the pylorus due to a food idiosyncrasy; this was obstructive and hindered the emptying of the viscus. Under normal conditions the pylorus was closed, opening under the influence of the alkalies below it. When the fluids of the liver and pancreas were deflected into the ileum, an ulcer arose in 70 per cent. of the cases.

The question of possible hæmorrhage entered largely into the selection of the operation to be done in a particular case. Hæmorrhage occurred in 24 per cent. of cases of ulcer of the duodenum, but in only 8 per cent. was the bleeding serious in degree. People with bleeding ulcer were best left to recover of themselves; they might go for any period from one to four years without further bleeding and then suddenly there might happen a severe attack of it. Perforation did not often occur in these cases. A point which would have to be decided in an individual case was whether the patient would suffer in the same way as if he had an active ulcer without hæmorrhage. These cases did well after gastro-enterostomy had been carried out. He did not think the hormone had much to do with the causation of this condition.

Conclusion.

In conclusion, Dr. Mayo said he thought doctors were more liable to acquire the closed mind than were most people. Travel had the effect of lessening the respect felt by a man for his own opinions; and he had been witnessing in this country beautiful operations which were done in a way quite different from that he was accustomed to. There were "many ways of going to the post-office," and the essential aim in surgery was to accomplish the needed result with the least possible danger to the patient.

The President exhibited by means of the epidiascope slides depicting the Mayo Brothers and views of their celebrated clinic and hospital.

On the motion of Sir James Berry (who received an ovation on his recent knighthood), seconded by Mr. Cyril Nitch, a cordial vote of thanks to Dr. Mayo for his address was carried by acclamation.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

At a meeting of this Section held on May 28th, Dr. John C. McVail, the President, in the chair, Dr. John Brownlee read a paper on the

Health of London in the Eighteenth Century.

Dr. Brownlee first of all exhibited tables making it probable that there was a considerable influx into London towards the end of the seventeenth century, but that thereafter, down to the end of the eighteenth century, the population was almost stationary and that the general rate of mortality (making allowance for the ageing of the immigrants at the end of the seventeenth century) also changed very little. In a general way, there was not much difference between eighteenth-century London and the most unhealthy urban area for which a life-table had been constructed in the nineteenth century—viz., Manchester township. Dr. Brownlee called attention to the increased proportional mortality from phthisis which the London Bills exhibited, and concluded that there was probably a real increase of phthisis in the last decades of the eighteenth century. He illustrated on the plague statistics of Bombay the movement in time of the maximum of an epidemic, and pointed out very remarkable changes in the seasonal incidence of mortality from convulsions and infantile diarrhœa in London. Mortality from measles was also illustrated.

In opening the discussion, Dr. Major Greenwood referred to the writings of Woolcombe, Sir Gilbert Blane, Sir James Clark, and Farr on the alleged increase of phthisis at the beginning of the nineteenth century. Blane's remark (made in 1815) that "consumptions have been observed to be more frequent of late among young adults, probably from a greater number of sickly children being saved," was of interest.—Dr. T. P. Beddoes thought the timing of an epidemic of plague was mainly dependent on the date of movement of stocks of grain.—Sir George Buchanan wondered whether the nomenclature of diseases in the Bills was sufficiently satisfactory for comparisons.—The discussion was continued by Dr. A. K. Chalmers, Dr. John Carswell, and the President, who all congratulated Dr. Brownlee on the great value of his contribution to the history of mortality in London.

SECTION OF LARYNGOLOGY.

On June 5th the Section of Laryngology held its summer meeting, and the whole day was taken up with papers, discussions, and the exhibition of cases. The chair was occupied by Dr. A. Logan Turner, President of the Section. Among the visitors welcomed by the President were Dr. Tapia (Madrid), Prof. Burger (Amsterdam), Dr. Charles Mayo (Rochester, U.S.A.), and Dr. Graham Brown (Brisbane).

Dr. Tapia read a paper in French on the Big Pharyngostomes as an Accident in Laryngectomy, how they could be avoided, and a method of closing them.

Sir StClair Thomson said Dr. Tapia's paper was founded on a very large experience, as he had done 151 laryngectomies. Before the war, when less was known about plastic surgery, one sometimes had to wait three months before the stoma closed.

Mr. Wilfred Trotter spoke on the subject of

Plastic Surgery in the Treatment of Malignant Disease in the Pharynx and Larynx.

He said the time had now gone when one could contemplate the removal of a malignant growth in this region and leave the patient to struggle with the necessary mutilation which ensued. The surgeon must consider, before undertaking such an operation, in what condition the patient was finally to be left, perhaps he must consider whether the kind of life it would leave him with would be worth having. The object of such plastic procedures was a double one. First, to restore as far as possible speech and swallowing. No one, he thought, could be content with surgical treatment of malignant disease of the pharynx and larynx which did not offer the patient a reasonable chance of maintaining to some degree his natural powers of speech and swallowing. Secondly, it was very important not to leave the patient immediately after the operation with any extensive raw surface upon which infection could occur, with its dangerous sequelæ of cellulitis in the neck and secondary hæmorrhage. In a favourable case of post-cricoid carcinoma the patient could be speaking and swallowing normally six weeks after the primary operation. Regarding the pharynx and larynx as a whole, there were four regions in which a plastic operation was needed and was practicable. The simplest case was that of carcinoma of the posterior wall of the pharynx, yet one could not remove even a small piece of this posterior wall without leaving a gap which had all the dangers of a raw wound. But a large section of posterior wall of the pharynx could be excised, and a flap of skin placed over the area, and the subsequent fistula could be closed in about three weeks. Plastic reconstitution was also needed after dealing with a growth in the near neighbourhood of the upper opening of the larynx when it was necessary to remove the party wall between the larynx and pharynx. In this case the division between larynx and pharynx must be reconstructed out of flaps of skin. Thirdly, plastic methods were needed when dealing with tumours of the larynx itself. The question had been discussed whether the whole larynx should ever be removed; certainly one could leave alone half or one-third of one cord, or even one arytenoid, without diminishing the chances of the patient. The raw surface should be lined with skin, then quite a good voice was generally preserved. The fourth region he referred to was the post-cricoid. A growth here could not be removed without doing a complete section of the cervical œsophagus. And the gullet must be reconstituted, otherwise there would be stricture, and the patient's convalescence would be a dangerous one. By preparing beforehand and doing immediately after the operation a plastic procedure, the patient was enabled to swallow normally.

Rules of Guidance.

Mr. Trotter said the surgeon must know before operating what kind of tumour he was about to deal with. He did not consider that the classification of these tumours of the œsophagus had received due attention. They could be separated off into exactly marked classes, so that the surgeon by examining the patient could recognise what kind of operation he was about to enter upon. Good plastic work could not be done in the pharynx and larynx unless a reasonable degree of asepsis could be secured. Otherwise there would be a good deal of scarring. There was reason for expecting much better results in edentulous patients than in those having many teeth, however healthy.

Mr. **LIONEL COLLEDGE** related a case bearing out Mr. Trotter's final contention as to the importance of these patients having all teeth removed. The patient was very reluctant to have more than one or two teeth removed, and the very partial success of the laryngo-fissure until all the teeth had been extracted, when there was no further hindrance, was very striking.

Sir **JAMES DUNDAS-GRANT** asked whether any members who operated on cases of the kind had ever attempted to allow them to heal by the open or partially open method. He was interested to note that when Mr. Trotter did a lateral pharyngotomy he stitched the deeper parts, but only partially closed the superficial part, so as to permit of the escape of secretions.

The Care of Diseased Conditions of Pharynx, Larynx, and Mouth.

Dr. **CHARLES MAYO** delivered a short address on this subject. He said that brief immersion of the unfertilised eggs of some lower types of life into sea-water to which had been added 1 per cent. butyric acid resulted in their fertilisation to a high degree, and this was interesting as showing the chemical side of stimulus to cell growth. In thinking of infection by a particular kind of organism it was well to inquire also what was the chemical composition of it and its place in the world. Warts and papillomata of mouth, vocal cords, bladder, rectum, and other parts, if irritated and subjected to ineffectual attempts at removal, became liable to malignant development. During the last two years in America there had been many cases of chronic hiccough, lasting three or four weeks. From the pharynx of these cases material was obtained which, when injected into rabbits, caused the same type of trouble. In people suffering from the somnolent form of encephalitis there was a redness of the pharynx, and as it was likely the mucous membrane of this region was very suitable to the causal organism, more attention should be paid to the mouth region in this disease. He believed that in his father's day ordinary clinical observation was carried to a higher perfection than in these days of elaborate laboratory and other aids. Sometimes the examination of a patient by the doctor did not include that of the tongue. The powers of observation to-day seemed to be slipping away. The large tonsil was never responsible for anything more than temporary trouble; the intermediate and the small tonsil were the danger, for in their crypts, unsuspected, they were harbouring an infection which was constantly being put into the blood-stream. The killing of tooth nerves by the dentist and the filling and crowning prevented the patient from feeling the danger-signal of pain when he had a septic focus in this region. In America there had recently been a tremendous increase in heart disease and in infections, and post-mortem examination seemed to show that much of this was fundamentally due to the teeth. Work had recently been done at Rochester on the production of stone in the kidney. Germs obtained from the grinding of bicuspid teeth of 12 people suffering from stone in the kidney were injected into animals, and in three months the X rays showed the beginning of most beautiful apical cavities in the bone, and in seven to nine months the rays showed stones in the kidney, of the same composition as those taken from the human subjects. In middle and late life people had troubles which were not due to pure infection, but to alterations of blood found at that period. Calcium was a great necessity, and he would like X ray pictures to be taken of teeth and jaws not only to see the amount of infection, but also as to the way Nature was handling her calcium in infected areas. There were periods of life in which we were resistant to certain infections. When a break came, a change was seen in the person's colour and appearance, so that it was not uncommon to see an old friend who seemed to have gone to pieces in the last two years due to a "blood break." The leucocytes of such a person would probably be found to be down to 55 per cent., or anything from that to 70 per cent. Inheritance was really a question of the degree of resistance, and how long the movable soil, the blood, could be maintained at the high degree of efficiency which enabled it to deal successfully with infections. A study of family history supplied an inkling as to what had specially to be contended with. After 40 years of age a trouble arose to which very little attention had been paid. In the case of every man over 45 massage of the prostate and seminal vesicles gave a fluid which contained one to three varieties of bacteria, not gonococci. And a woman who had a very large cervix was carrying organisms not in the mucous membrane—though two or three varieties were there always—but just behind the mucous membrane. It might be the type of germ which would produce fibroids, as he did not doubt that fibroids were produced by chemical irritation originating in bacteria which did not raise the temperature. One should not give up treating cases of rheumatoid arthritis and chronic conditions of the nervous system without testing and investigating in this newer field—the cervix in women, the prostate and the seminal vesicles in men.

Speech After Laryngectomy.

Prof. **BURGER** read a contribution on the means of restoring to patients whose larynx had been completely removed some measure of speech, and brought with him a male patient on whom this operation had been done, for the meeting to judge of the effects of the means employed. Prof. Burger formed a pseudo-glottis at the mouth of the œsophagus, and during quiet respiration the mouth of the œsophagus was always wide open. The patient gave a remarkable demonstration of his powers—modulating his low-pitched voice, whispering, whistling, smoking, and ejecting the smoke through his nose, &c. After fatigue, such as after going upstairs, the voice was appreciably weaker. His efforts were far less successful when he was not wearing a stiff collar to give support to the neck. After each few words the act of swallowing had to be carried out.

Mr. **Lionel Colledge** demonstrated the McKenty-Western artificial larynx, and exhibited two patients who were using it. A pad fitted over the opening of the trachea was fixed in position by means of tapes, which were passed under the axillæ and round the neck. In other respects this artificial larynx closely resembled that of Dr. Tapia, except that the chamber was a little larger than his, and there was a screw by which the tension of the membrane could be adjusted. He described the operations which were done on the two patients, one last year, the other four years ago.

Mr. **R. Graham Brown** (Brisbane) also exhibited an artificial larynx. He said the great difficulty in these cases was to overcome the escape of saliva around the opening of the artificial larynx. So great was the discomfort due to this that most surgeons were content to do without aids to voice production. By means of the apparatus now shown an excellent voice resulted, which filled an ordinary room, the apparatus was cheap, and there was very little escape of saliva over long periods. The speculum was of gold, as silver was subject to erosion.

Dr. **Tapia** showed his apparatus which he designed for the same purpose. He said the ideal of function was to speak without the help of apparatus. He had several patients who, after laryngectomy, could speak as well as Prof. Burger's patient. By means of his own apparatus patients could speak correctly on the third day. One, a lawyer, continued in the practice of his profession without any unusual fatigue. Dr. Tapia and his son proposed to make a subcutaneous tubular connexion between the neck and the mouth to replace the tube which the patient now placed in the mouth.

Sir **James Dundas-Grant** showed a young female patient whose larynx he removed two years ago and who now had no voice whatever. She had, however, such remarkably clear articulation that she could be well understood and was able to do her own shopping without writing her wishes.

Prof. **Burger**, in reply, said his patient was not an exceptional case, and the mechanism of speech was the same as that in the normal man.

Tracheotomy in Tuberculous Laryngitis.

This subject was dealt with in a paper by Dr. **Ritchie Rodger**. In November last, he said, in a discussion at a meeting of the Section, Sir StClair Thomson suggested the more frequent use of tracheotomy in cases of tubercle of the larynx. Dr. Rodger now narrated four cases in which tracheotomy was urgently called for in order to avoid a fatal issue. The root treatment of tuberculous disease in all parts of the body capable of movement was to place the affected parts in a state of physiological rest as far as possible. Resting the voice completely was very important in laryngeal tuberculosis, but there was a movement of the larynx during every act of deglutition also, not only in taking food, but in swallowing saliva, as well as the usual small movement during respiration, and closure of the glottis during a number of forced muscular actions. Records given by Sir StClair Thomson and others showed that the normal lung was not prejudiced by the wearing of tracheotomy tubes. He agreed, however, that a patient wearing such a tube found difficulty in getting rid of his sputum. When the disease involved only the mucosa there seemed no reason to expect that the wearing of the tracheotomy tube would have to be continued for very long.

Sir **James Dundas-Grant** thought that in the cases described by Dr. Rodger the procedure of tracheotomy was called for and was fully justified. But one would hesitate to do it where there was no serious stridor or obstruction. Much would depend on the condition of the patient's lungs, and if they were only slightly affected tracheotomy could be done. The maintenance of absolute silence gave extraordinarily good results in many cases of this disease.

Mr. **E. D. Davis** said he and his colleagues always tried to avoid tracheotomy for the condition for two reasons. One was because the tracheotomy wound became very septic, and the other was that the patient had a good deal of coughing, and it was this which did most damage to the larynx. Rest was the most important necessity.

Sir **StClair Thomson** said he considered that tracheotomy, as a curative method, was seldom called for in tuberculosis. In 450 cases of tubercle of the larynx at Midhurst Sanatorium, he had had to do tracheotomy for dyspnœa to save life only two or three times. One patient, a doctor, declined it when it was recommended to him, but later he had to have it done, and shortly afterwards he died. People could have tubercle and die of it without tubercle bacilli being found in the sputum.

Dr. **P. Watson-Williams** said tracheotomy gave much relief in this disease when there was considerable dyspnœa, but he had never seen a case in which one could imagine it would be a means of saving life for more than a short time. He thought the disadvantages alluded to by the reader of the paper outweighed such advantages as could be attributed to tracheotomy.

Dr. **Douglas Guthrie** spoke of a case in which a woman with advanced tuberculosis of the lungs was in danger of asphyxiation in the early stages of labour. Tracheotomy was performed four hours before the birth of the child, and the subsequent course of the labour did not seem to have been adversely influenced.

Intranasal Dacryocystostomy.

Dr. **J. S. Fraser** (Edinburgh) read a short paper on this subject. He said that often patients with dacryocystitis did not come for treatment until the disease had reached an aggravated form, with much dilatation of the sac by muco-pus, or with a tear-sac abscess. Dilatation of the tear passages by frequent probing was mostly ineffective, and only moderate success attended the use of drainage threads. Most ophthalmic surgeons seemed to prefer to excise the tear-sac completely; but following this there was persistent eye-watering. Dr. J. V. Paterson, of Edinburgh, found the best results followed the intranasal operation. In 47 operations the duration of the dacryocystitis varied from three months to 20 years, and most of the patients were between 30 and 50 years of age. The majority of the patients had had previous treatment by dilatation of the punctum and canaliculus, washing out of the tear-sac, and the passage of probes into the nose. The trouble had probably been due to infection having passed up the nasal duct into the nose. Dr. Fraser described the operation in detail. No after-treatment was necessary, and the average stay in hospital was only four days. Recurrence of the dacryocystitis took place in about 25 per cent. of the cases, and when this was less than two months after the operation it was due to failure to remove enough of the inner wall of the tear-sac.

Mr. **J. B. Horgan** (Cork) said he had been doing for a period of 12 years the operation Dr. Fraser had described, and his experience corresponded in the main with Dr. Fraser's. But he did not do it under general anæsthesia; he put into the sac a few drops of cocaine and adrenalin solution. He found it a considerable advantage to resect the anterior part of the nasal septum in every case; it gave to the operator a better field, and no harm seemed to come of it. The stenosis met with in the naso-lacrymal duct he believed to be due to a latent infection of the anterior ethmoidal cells. He showed the instrument he used.

Mr. **Lawson Whale** considered that if it was felt necessary to resect the septum, this should be done as a separate preliminary operation, never at the same time as the primary one. Pressure on the inner canthus should not be by the finger, as mentioned; it was much better to use a large-sized bone probe for forcing the bone. To obviate slipping, he had devised an instrument like a golf mashie, but turned back the wrong way. His own criteria of success were: That if after the operation the eye never watered in a strong wind outside, it was a complete success; if it did not water except in a strong wind, it was a modified success; if it watered at all, even indoors, it was a failure.

Mr. A. J. M. WRIGHT (Bristol) contended that there was no need to do the septal operation at a time other than that of the primary operation.

Mr. J. W. HARRISON said the bone should be removed in only thin pieces. Otherwise there would be splinting and extra granulations formed. His practice was to make a large hole from above downwards, then re-formation rapidly took place. The operation should not be done when the condition was in an acute stage, but when it had definitely begun to subside.

Mr. E. D. DAVIS said his colleagues at the Westminster Ophthalmic Hospital were not very satisfied with the results in these cases, especially those which had an acute suppuration of the lacrymal sac. And the chronic cases were liable to have stenosis of that sac, and the operation had to be done again.

Dr. GRAHAM BROWN, speaking as both an ophthalmic and a nose surgeon, said he had no compunction in doing the external operation. There were considerable difficulties connected with the internal operation. He did the operation under local anæsthesia.

Dr. FRASER, in the course of his reply, agreed with Mr. Whale's criteria, and said the cases he classed as successes had no watering of the eyes in any weather, either indoors or out.

The Sinus Condition in Encephalitis Lethargica.

Dr. A. LOWNDES YATES, in a paper on this subject, said that in the cases investigated the pneumococcus or the bacillus of Friedländer was usually found, and in all the patients there was rhinitis and sinusitis generally affecting the mucous membrane in or around the posterior group of sinuses, chiefly the sphenoidal. The membrane seemed to have lost its function, there was ciliary paralysis, and fluid put into the posterior part of the nose was not removed by the ciliated epithelium. Mucus was absent, and the sinus contained a material, not colloid, resulting from the digestion of the normal mucus by bacterial action. There were comparatively few sufferers from encephalitis lethargica, but many carriers. The filter-passing virus seemed to need to fall upon mucous membrane which had been altered by influenza or chronic rhinitis in order to produce the symptoms of the disease. Treatment of the nasal condition by eucalyptol and paraffin seemed to have been distinctly beneficial and was worth a trial.

Dr. P. WATSON-WILLIAMS regarded this as pioneer work, and said it was necessary to carry the work further before one could feel one was on sure ground. One real difficulty was to be sure of the diagnosis of encephalitis lethargica.

Demonstrations.

Dr. LOGAN TURNER and Dr. F. E. REYNOLDS submitted a contribution illustrated by a number of slides to show the path of infection in a case of nasal furuncle which led to thrombosis of the cavernous sinus. The patient's temperature reached 106° F., the eyeballs were immobile, and he died after a fulminating illness of only seven days' duration. The post-mortem examination showed that the frontal and the maxillary sinuses were normal and that a septic thrombus of the superficial plexus, passing into the ophthalmic vein, led to the detachment of a small septic thrombus, which was caught up in the cavernous sinus and caused a septic thrombosis. Dr. Reynolds demonstrated the photo-micrographs.

Mr. COLLEDGE gave an instructive demonstration by kinematograph of an experiment carried out on a gibbon by Sir Charles Ballance and himself. Anastomosis of the phrenic nerve restored the mobility of a cord which had been paralysed.

Clinical Cases.

At the afternoon session a large number of cases were demonstrated and discussed.

Dr. DOUGLAS GUTHRIE showed a man, aged 30, with a tuberculoma of the tonsil. He had never had tonsillitis nor any chest symptoms. Wassermann was negative. The tumour was dissected out and was limited by the tonsillar capsule. It was of the size of a walnut. The microscopic section exhibited revealed chronic fibrosis and numerous typical tuberculous deposits.

Dr. JOBSON HORNE showed a man, aged 63, who had complained of his throat for ten years, but there was no voice impairment. Pharyngitis explained the throat symptoms. On the right vocal cord was an excrescence, and on the left cord, at the vocal processes, a dimple.

Sir JAMES DUNDAS-GRANT showed the specimen of an extrinsic laryngeal epithelioma which Mr. Wilfred Trotter removed from a man aged 57.

Mr. C. A. S. RIDOUT exhibited a male patient, aged 53, on whom he did a laryngo-fissure for squamous-celled carcinoma of the left vocal cord in February, 1922. A recurrence five months later was removed by complete laryngectomy preceded by tracheotomy. The patient had since remained in excellent health.

Mr. HERBERT TILLEY showed a man, aged 20, whose tracheal stenosis following diphtheria in infancy had been treated by a dilator formed by fine air-filled drainage-tubes. With the cannula corked the patient could breathe through the larynx for five hours at a time. He also exhibited a female patient whom he had cured of tuberculous laryngitis by means of galvanopuncture.

Several cases were also shown by Mr. LAWSON WHALE, Mr. F. F. MUECKE, and Dr. DAN MCKENZIE.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held at the rooms of the Medical Society of London on May 29th, Colonel L. W. HARRISON, the President, in the chair, when the subject for discussion was the

DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES IN PREGNANCY.

Sir HENRY SIMSON, in opening the discussion, said he hoped chief attention would be devoted to gonorrhœa in pregnancy, as it had received less attention of late than had the complication of syphilis.

Gonorrhœa in Pregnancy.

Dealing first with gonorrhœa, he said that a woman who contracted gonorrhœa at the same time as she became pregnant could be considered lucky so far as the disease was concerned, because the path to the peritoneal cavity soon became closed, and valuable time was allowed for the cure of the gonorrhœa before parturition took place, and mostly, when adequate treatment had been given, a normal child was born at due time. It was a different story if a woman became pregnant subsequent to contracting gonorrhœa, and these were the cases which were so often seen at the V.D. clinics. Here the woman had had gonorrhœa for some time, but, with douching and permanganate irrigation, she had remained comfortable. When pregnancy set in, the congestion and the reactions of the pregnancy immediately set up an acute recrudescence in her of the gonorrhœa. The disease was now no longer confined to the vagina, the whole cervical canal was involved, and probably the uterine cavity too. And such a woman was more difficult to treat and was very liable to miscarry. Miscarriage was a very serious complication of gonorrhœa. In a nulliparous unmarried woman gonorrhœa was an eminently curable condition; there was no husband to treat, and intercourse was easily prevented. It was of the utmost importance to cure these women before they became pregnant. Over 75 per cent. of cases of pelvic gonorrhœa were in women who had become pregnant with an uncured gonorrhœal vaginitis. Whenever a pregnant woman complained of leucorrhœa it was essential that she should be examined most carefully so as to exclude gonorrhœa if possible: this was the stage at which the diagnosis should be made and when treatment was most hopeful. The most likely place in which the gonococcus was to be found was in Skene's tubules and in the urethra, and it should be sought by direct examination of a specimen obtained by the platinum loop; it would be useless to send specimens to the laboratory as the organisms would not survive.

Ambulatory Treatment.—When a pregnant woman was found to be suffering from gonorrhœa, it was unavailing to attempt ambulatory treatment; the patient must be kept in bed for at least three weeks. The disease might then be cured before the pregnancy came to an end.

Syphilis in Pregnancy.

Sometimes a woman gave birth to a syphilitic child without herself having had obvious symptoms of the disease. On the other hand, pregnant women sometimes had very severe secondary syphilis. He still believed that fœtal infection was not always transplacental. There were four classes of cases to be dealt with. In the first class a woman contracted syphilis at the same time as she became pregnant, and in the second she contracted the disease subsequently to becoming pregnant. In these kinds of case the fœtus was infected through the placenta, and the woman had been infected by a man when he was suffering from a primary sore or from secondary syphilis. In the third class of case the woman had had syphilis some time before becoming pregnant, and when the latter event occurred she showed no fresh symptoms of syphilis. Here also she infected the fœtus through the placenta and gave birth to a syphilitic child, although her husband might never be infected. In the fourth class the same sequence held good. A man was an old syphilitic; he might live with his wife for a year without infecting her, but when she became pregnant the embryo was syphilitic through parental infection. The symptoms of the disease in the mother were markedly modified and were often difficult to detect. From the standpoint of the public health it was very important to ascertain what was the result of treatment in these four classes of case. What was likely to be the result of treatment on the fœtus? The prognosis in regard to the fœtus in the first and second classes he considered to be much better than in the third and fourth. If a woman with acute secondary symptoms were properly treated before the fifth month of her pregnancy she was almost certain to have a healthy child with a negative Wassermann. And a woman infected after the third month of pregnancy would probably have a healthy child, as the shortness of time and the placental barrier protected the fœtus. Were the cases of juvenile general paralysis likely to be more numerous because an 80 per cent. mortality from infantile syphilis could be prevented?

Gonorrhœa and Pregnancy.

Mr. **Aleck Bourne** said he saw the patient with venereal disease who was pregnant because of her venereal disease, and his remarks would be confined to pregnancy complicated by gonorrhœa. In pregnancy there were two sharply defined types of gonorrhœal case. One was the acute case, in which the patient contracted the disease after becoming pregnant. In these there was frequently an acute vulvitis, with œdema of the labia, a muco-purulent discharge, pain, frequency, and smarting in connexion with micturition. This type was less frequent than the chronic type, in which there was but little exacerbation of the condition of gonorrhœa, and the patient had perhaps been infected for years by the gonococcus before becoming pregnant. In this form his experience had been that after a few weeks of pregnancy the gonorrhœa had settled down, the symptoms disappeared, and it was very difficult to detect the condition by clinical methods. It was commoner to find the gonococcus in patients who had only a mucoid discharge than in those in whom the discharge was purulent. If a specimen taken from the patient was positive in regard to gonococci, the cervical canal was swabbed out with a 10 per cent. solution of formalin; this was a very penetrating solution for the tissues, and was a very efficient bactericidal agent. The vagina was swabbed out with picric acid and the urethra with protargol. An aid to the diagnosis of gonorrhœa in pregnancy was the effect of treatment—i.e., the rapidity with which the discharge cleared up under treatment. A large number of patients with uncured gonorrhœa in pregnancy went through their gestation and puerperium without anything abnormal occurring except, perhaps, a transient rise of temperature during the puerperium, and a little sapræmia. But in others there seemed to be a good deal of danger to the patient, though in actual fact the danger in pregnancy was slight. The uterine ostea and Fallopian tubes were closed at an early stage of the pregnancy and the peritoneal cavity was thus sealed off. The only case of general gonococcal septicæmia during pregnancy he had seen was that of a patient who became infected with the disease during her pregnancy, and she died of the generalised disease. After labour the child's eyes were treated with a 1½ per cent. solution of silver nitrate, which was on the strong side; perhaps 1 per cent. was equally good. His experience was that the gonococcus only gave rise to acute salpingitis if it was accompanied by the streptococcus. If the gonococcus alone was responsible for a salpingitis, his view was that it came on much later than the seventh day of the puerperium.

Dr. **Dorothy Logan** spoke of her experiences at the Mothers' Hospital at Clapton, where mothers came in for their confinement. They entered the institution three or four months before the event and stayed for some time afterwards. An acute case of venereal disease in pregnancy was put to bed. A routine treatment for the gonorrhœal cases was to swab well with protargol. Combined with glycerine she had found it most useful. A pack of 10 per cent. protargol was left in situ. In dirty cases this treatment was applied twice daily. She did not pack the cervix, but applied protargol as high as she could. Cases seemed to clear up better, on the whole, if the treatment was reinforced by vaccines. She had not seen many cases of acute complication in the tubes, nor of sepsis associated with pregnancy. Cases of venereal disease treated for some time before labour showed, on the whole, less morbidity in the puerperium than cases not so dealt with. The gonococcus was more frequently found in the apparently clean cases than in the cases which had a greenish purulent discharge, particularly after confinement.

Dr. **Margaret Rorke** agreed that the serious cases mostly showed streptococci and staphylococci associated with gonococci. These cases seemed to do well up to a point, beyond which they seemed to progress no further. At actual delivery there was very little trouble, and little or no rise of temperature occurred. She had noticed, however, that though the mother was kept in bed 12 or 14 days, and the child was fed at the breast, the gonococcal cases did not involute as the ordinary uninfected cases did, the uterus remaining large and bulky for weeks afterwards. And many of these cases tended to have retroversion, which aggravated the menorrhagia. The third class of cases to which Sir Henry Simson referred had been found in her hospital to be a tiresome class. There was a large class who during the war became infected with syphilis, had only a moderate amount of treatment, who married subsequently and would be having children. These, not knowing the disease was still present, would not have treatment during pregnancy, and there was likely to be a crop of syphilitic children. She had a great liking for lactic acid in gonorrhœal cases. She had so far hesitated to use milk injections in pregnancy.

The PRESIDENT said he was glad to hear it advocated that the woman who showed signs of leucorrhœa during pregnancy should be examined culturally and bacteriologically. That advice he would like to see broadcast throughout the country; it would do much to clear up gonorrhœa in a general way and to lessen the incidence of ophthalmia neonatorum. Also, was it not likely to prevent some of the puerperal morbidity? The association of the streptococcus with the gonococcus in puerperal tube trouble was a matter of considerable interest. He supported Dr. Logan's view that women suffering from gonorrhœa who had been treated steadily throughout the period of their pregnancy did extraordinarily well during the puerperium. If this course were more general, a good deal of puerperal mortality would probably be prevented, for that was so often due to streptococci which were able to gain a footing and flourish because the soil had already been prepared for them by the gonococcus. All these facts strongly supported the contention that every woman who was found to be suffering from leucorrhœa should be thoroughly examined. And in that investigation he advanced a strong plea for taking cultures; for very often a slide showed a negative result when cultures gave a positive one. At St. Thomas's Hospital the cervical canal was not touched during pregnancy; the staff there contented themselves with placing pledgets against the cervix, so as to promote the outflow of pure serum. They had a fear of provoking a premature termination of the pregnancy.

The openers briefly replied.

Reviews and Notices of Books.

ENCYCLOPÆDIA MEDICA.

Second edition. Under the General Editorship of the late J. W. BALLANTYNE, M.D., C.M., F.R.C.P.E.; and ALEXANDER GOODALL, M.D., F.R.C.P.E. Vol. XII.: *Tularæmia to Zinc.* Supplement. Edinburgh: W. Green and Son, Ltd. 1925. Pp. 671. 30*s.*

THE second edition of the Encyclopædia Medica is completed with this volume, which contains, besides a number of new and rewritten articles in the substance of the book, a special supplement dealing with the modern treatment of diabetes and an article on respiration by Dr. Whitridge Davies. In the former Dr. C. G. Lambie gives a valuable résumé of the principles governing diabetic dieting under insulin, and a complete diet table which will be of much value to practitioners who have little time to work out calories for individual patients. The article on X rays and radium, by Dr. R. Knox, is illustrated by very beautiful plates.

A large part of the volume is concerned with genito-urinary diseases. Articles on the urachus by Prof. A. W. Shee, on uræmia by Sir Nestor Tirard, on the urethra and venereal diseases by Sir D'Arcy Power, on the urine by Dr. Lambie, on the uterus by Mr. A. E. Giles, Mr. G. S. Davidson, Mr. W. F. T. Haultain, Mr. Comyns Berkeley, Miss Louisa Martindale, and Mrs. Mary Scharlieb, on the vagina by Prof. T. Wilson, and on the vulva by Mr. Giles are included. Of the infectious diseases typhoid, typhus, undulant fever, varicella and whooping-cough, yaws and yellow fever are considered, together with articles on vaccination and vaccine therapy. Public health matters are represented by articles on water and vital statistics. The account of visceral pain by the late Sir James Mackenzie will fulfil the expectations of his disciples. A new short account of vitamins has been provided by Dr. Marshall Findlay. An excellent account of urticaria by Dr. J. M. Macleod is a new feature in this edition, as is also the article on unconsciousness by Dr. T. Hyslop.

The concluding volumes of this work have not been allowed to suffer through the death of the editor chiefly responsible for the earlier ones, and it can be recommended as a balanced encyclopædia of the medical knowledge of our times.

ANÆSTHESIA.

Second edition. By J. T. GWATHMEY, M.D. London: J. and A. Churchill. 1925. With 273 illustrations. Pp. 799. 25*s.*

Dr. Gwathmey's book is well known on this side of the Atlantic. The present edition is continued on the lines of the first, but with certain important omissions which, in our opinion, greatly improve the volume. The original book was not easy to read, partly, no doubt, because of that lack of continuity which is inevitable where many collaborators take part instead of a single author, but partly, also, because it was overloaded with statistics, a feature nowhere less satisfactory than in a work on anæsthetics. The statistical chapter is omitted entirely in this edition. There is less justification for removing the chapter on mental influence and hypnosis, for these processes have much theoretical as well as some practical value. Important new matter has been added. Synergistic analgesia and anæsthesia, with special reference to magnesium sulphate, receive a chapter to themselves, as is natural with a branch of work for which Gwathmey has been mainly responsible. By synergism the author denotes the reciprocal augmentation of the action of one drug by that of another. He contends that the effect of the synergistic action of drugs is not due to a simple summation of similar pharmacological actions, but we confess to finding no proof of this assertion; indeed, it appears to be a proposition highly difficult to demonstrate. When a condition of analgesia or of anæsthesia is produced by the combined action of two or more drugs, each of which can alone produce the condition to some extent, how are we to know to what exact extent each drug is responsible in the state finally obtained by their combined action? With regard to magnesium sulphate, it is interesting to read that subarachnoid injection produces in animals nearly immediate anæsthesia and paralysis of the extremities.

Details are given of laboratory experiments in a chapter which contains one observation which will puzzle many readers: "The fact, well known to anæsthetists, that nitrous oxide, the least harmful of the general anæsthetics in its effects upon the tissues and organs of the body, is dangerous when used alone." It is generally held, we believe, that apart from asphyxia nitrous oxide alone is free from danger. The technique of synergistic anæsthesia is elaborate and involves so many hypodermic and rectal injections that its advantages should be very great to justify the amount of manipulation to which the patient is subjected. However, Rector, after his experience of 2000 cases, is well satisfied with the method. Meltzer found that the heart remains normal during anæsthesia from magnesium sulphate, and that the danger of this agent is its effect on respiration. In synergistic anæsthesia it is used in 4 per cent. solution, some 200 to 400 c.cm. being instilled by hypodermoclysis. A fatal case is quoted from Curtis after 310 c.cm. of a 4 per cent. solution, but Gwathmey disagrees with Curtis as to the cause of the death, because the post-mortem examination revealed profound changes in the liver, and these do not occur in laboratory animals even when magnesium sulphate is given in sufficient volume to kill.

The general physiology of anæsthesia is fully discussed in a chapter of over 60 pages, and special chapters by collaborators are on local anæsthesia as applied in dentistry, on the use of rebreathing (W. B. Gatch), on intravenous anæsthesia, and on ethylene anæsthesia. With regard to the latter drug A. P. Luckhardt states that it is the anæsthetic of choice for elderly subjects undergoing urological operations, and also for diabetics. Over 1100 cases without fatality are reported. Oozing from the wound and the explosibility of the gas are given as the two chief drawbacks to ethylene.

This edition should prove popular to readers in this country as well as in the United States.

MIDDLE AGE AND OLD AGE.

By LEONARD WILLIAMS, M.D. London: Humphrey Milford. Oxford University Press. 1925. Pp. 296. 10*s.* 6*d.*

IT is in the very nature of technology, no matter in what science or art, that it should itself be dull. This must be so, and the sensible writer will not try to offend the natural order of things by forcing a breeziness of style into his technical description that has no right to be there, but will be as brief and accurate as possible and keep his humanity for the application of his hard-won knowledge to the problems of human life. For his general observance of this working rule Dr. Leonard Williams deserves praise. His book is not technical as medical works go, but a considerable amount of technique has been skilfully inserted into his essay, never too much at a time; when, however, he is for the moment released from it his style becomes delightful.

It is unnecessary to remind our readers that Dr. Williams is first and foremost a dietitian; he is, secondly, a bold and humorous lover of controversy; and, thirdly, from his years of experience as medical adviser to a large life insurance company, he has learnt a great deal about the pathology of old age. These three qualifications make him peculiarly fitted to write on such a subject as middle age and old age. He explains in his preface that, since the subject of old age is inseparable from the condition of middle age that introduces it, and since a complete survey of these two states would amount to an exhaustive study of medical practice, his book is a compromise, its object being to show the best way to a happy old age and the most useful weapons against the diseases that beset middle age. In the second half of his aim he has attained a considerable measure of success. He has discussed clearly and well every one of the common ailments that cause so much suffering to those who have passed their prime, and he has drawn on the latest result of research, notably in the treatment of diabetes, carcinoma, and chronic intestinal stasis, in order to arm the practitioner with the means of helping his patient over this exacting period.

Whether he has been successful in his first aim is a matter open to question. Dr. Williams sees chronic intestinal stasis as the supreme enemy of the aged and the first cause of every one of the troubles incident to that stage of life. The stasis is, he argues, directly due to the action of toxins, which are present in intolerable force owing to excessive and unsuitable feeding during the whole period of active life. They fortify their attack by causing kinking and distortion of the colon, and they work the endocrine system to an early retirement, thus completing the vicious circle. Therefore, if we would live long, our bill of fare must be drastically revised, both for quantity and quality. Dr. Williams attacks our four meals a day so effectually that scarce one survives. We may have a continental breakfast, with honey if we are good; a bread-and-cheese lunch, with the concession of some harmless egg dish, if we must; he will not hear of afternoon tea, that real and never-failing comfort of the elderly, and even dinner is not spared from this ruthless savagery; our butcher's meat is replaced by expensive fish or game, and our beloved puddings are gone, never to be restored. We may have fruit salad, but no sugar with it, for cane sugar is a disaccharide and quite indigestible. A cheese savoury or something equally harmless is allowed to round off the meal, but we ask in vain for our cup of coffee. We may have alcohol in the strictest moderation at this meal alone. His salads, while distinctly attractive as a supplement to our ordinary meals, horrify us as substitutes, and his three-day fasts and venesection (his advocacy of which is affectionate almost to gloating point) bring home to us the inner truth of the saying, "Those whom the gods love die young."

We cannot dispute the accuracy of a single one of Dr. Williams's statements, yet we doubt whether old age at such a price is worth having. But the real value of the book is unquestioned, if only for its admirable chapters on the endocrinology of middle age and the climacteric in women.

CANCER PROPAGANDA.

Cancer and the Public. By CHARLES P. CHILDE, B.A., F.R.C.S., M.R.C.P.E., Consulting Surgeon, Royal Portsmouth Hospital. London: Methuen and Co., Ltd. 1925. Pp. 267. 10*s.* 6*d.*

IN this book, which is dedicated to the public, the author has presented those practical aspects of the cancer problem which are of special interest to the public in such a way that they can be understood by every intelligent reader. He emphasises in particular that cancer is a curable disease if treated surgically in its earliest stages. He points out that cancer has no characteristic symptoms and that therefore the disease, especially in its earliest stages, cannot be diagnosed with certainty except by microscopic examination after operation. He indicates the various "danger signals" that may make us suspicious of the presence of cancer, and urges the public not to delay in asking for medical advice if any of these symptoms are noticed. He disposes of the various fallacies and errors which have come to be associated with cancer in the public mind, such as the relation of cancer to diet, and he concludes that cancer is not infective and that cancer-houses are a myth. He also discusses the limitations of radio-therapy.

The book is written in such a lucid and sane manner that it could be recommended without reserve were it not that in the concluding chapter Mr. Childe raises a highly controversial subject in pleading for establishing a cancer propaganda based on the model of the American Society for the Control of Cancer. This question was discussed a year or two ago at the Royal Society of Medicine without meeting with general approval. This is not the place to discuss the objections to such a propaganda: it must be sufficient to say that they are based on more substantial grounds than indifference and lack of initiative on the part of the medical profession, as the author suggests. It is unfortunate that a book of 260 pages of large print without expensive figures or tables, which is intended for the instruction of the public, should be published at such a high price as half a guinea.

The Conquest of Cancer. By H. W. S. WRIGHT, M.S., F.R.C.S. With an Introduction by F. G. CROOKSHANK, M.D., F.R.C.P. London: Kegan Paul, Trench, Trübner and Co.; New York: E. P. Dutton and Co. 1925. Pp. 86. 12*s.* 6*d.*

THE lesson which Mr. Wright emphasises throughout this convincing little book is the good prospect of cure by surgical means of a patient suffering from cancer at an early stage. It is indeed to those patients who are not consciously suffering anything but the inconvenience of a persistent pimple or the irritation of a small ulcer, and to their friends, that his propaganda is chiefly addressed. There is a breezy optimism throughout the volume which adds considerably to its value for lay reading, but hardly ever is the author led by his enthusiasm to protest or to promise too much. The importance of chronic irritation as a factor in the ætiology of cancer is now generally admitted; the author regards as equally important "the presence of an acid environment" (p. 54), but does not explain the grounds on which he bases this impression. The use of the term pre-cancerous stage is not well-advised, since until malignant cells are actually visible in a microscopic section of a tumour or ulcer it is not possible as yet to recognise any lesion which will assuredly give rise to them. In discussing X ray and radium therapy, other than palliative, Mr. Wright points out that no figures are of any value till seven years at least have elapsed after treatment. The dictum as to a seven years basis for reported cures should be noted by surgeons, who are too apt to regard three years as a sufficient margin. Most of the highest authorities on radio-therapy are, however, agreed that in operable cases surgery should be the first resort.

It is no easy task "to enlighten the laymen, that their help may be enlisted, and yet to avoid alike exaggeration and smooth sayings, false hopes, and false fears" on such a controversial subject as the conquest of cancer. Dr. F. G. Crookshank introduces Mr. Wright to the public as one who has performed this task fairly and lucidly, and we agree with the verdict.

New Cancer Facts. By DAVID MASTERS. With an Introduction by Sir JAMES CANTLIE, K.B.E., F.R.C.S. London: John Lane, The Bodley Head. 1925. Pp. 84. 2*s.* 6*d.*

Mr. Masters, who has been successful in fascinating a large number of readers with the romance of excavation and the wonders of salvage, has more recently attempted to present in equally attractive form steps in the conquest of disease. His latest book, under a title somewhat too precise, is largely devoted to special pleading on behalf of the parasitic theory of cancer, of which he is a spirited if not very judicial advocate. Indeed, his enthusiasm would seem to have been aroused less by the theory in abstract than by the personality of Dr. Louis Sambon. It is with the conclusions of this observer, from work in Italy and Iceland, that the book is largely concerned; attempts by Dr. James Young and by Dr. Glover to demonstrate the causal parasite are held still to be unproven. Brief mention is made of the filter-passers wherefrom Peyton Rous was able in 1911 to produce sarcomata in chickens. The recent repetition and extension of this important work by Dr. W. E. Gye in this country, reported in last week's LANCET, may well lead to a reconsideration of the parasitic theory of cancer from an entirely new aspect. It may be long, however, before such definite conclusions are reached as can be set out with profit in a small handbook designed for the layman. The problem is unfortunately less simple than it appears to Mr. Masters.

LECTURES ON PATHOLOGY.

By LUDWIG ASCHOFF, M.D., Professor of Pathologic Anatomy, University of Freiburg. New York: Paul B. Hoeber. 1924. Pp. 365. $5.

THESE lectures were delivered by Prof. Aschoff in America during the spring of 1924. They are 14 in number and deal with a variety of subjects, including the pathology of gall-stones, the pathological metabolism of fat, the goitre problem, the pathology of gastric ulcer, the parthogenesis of human pulmonary consumption, and the reticulo-endothelial system. Prof. Aschoff is one of the greatest living authorities on morbid anatomy, and has particular claims to speak on the subjects he has chosen. The publication of these lectures in book form will, therefore, be welcomed by all pathologists. Freed from the dogmatism which the writer of a student's text-book must maintain, Prof. Aschoff is able to deal with his matter with breadth of view and a wealth of detail which would be out of place in a more elementary publication. Above all, he is able to give his individual opinion full rein, and to indulge in a valuable personal contribution to pathological teaching.

In reading these lectures one cannot fail to be struck by the enthusiasm which has done so much to make Germany the home of morbid anatomy. The author's interest never flags; even during the war he continued to be a student of academic pathology, utilising the facilities afforded by his position as army prosector to make observations which could scarcely have been possible in normal times. The lectures have been rendered by anonymous translators to whom the author gives thanks in his preface, and the occurrence of an occasional phrase like "a comprehensive understanding of this clinically so important disease" bears witness to the fidelity of the translation.

JOURNALS.

QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE. Vol. LXIX. Parts I. and II.—The two latest numbers contain 15 memoirs on a large variety of subjects by authors nearly all of whom are recent workers in zoology. The exception is an article by Dr. Arthur Bolles Lee, a well-known authority on microscopical technique, who writes upon the chromosomes of *Paris quadrifolia*.—A paper on the development of the skull of the sole and the plaice, with good figures of the young and symmetrical skull, is from the zoological laboratory of the University of Bristol, by Dr. N. J. Berrill.—A short and clearly illustrated account is given by Mr. E. Percival (University of Sheffield) of a new British land planarian, *Rhynchodemus britannicus*, of which a specimen was lent to the author by Dr. Dendy, whose recent death is a great loss to zoology. This animal is one of three species known to be indigenous to this country; one other, introduced from the tropics, is fairly common.—Mr. N. A. Macintosh describes the crystalline style of *Crepidula fornicata* and comments upon this structure in other gastropods, comparing them with the much better known and more generally occurring crystalline style of lamellibranch molluscs. All the contents are of interest.

QUARTERLY JOURNAL OF MEDICINE.—The April number contains the following articles: The Blood-urea and its Estimation in Diabetes Mellitus, by Charles E. Brunton. Observations on the blood-urea and blood-sugar concentration in cases of diabetes treated with or without insulin did not reveal any relationship existing between them. The administration of insulin did not appear to affect the blood-urea content. It was found that diabetic coma is not necessarily accompanied by a high blood-urea figure, and the amount of urea in the blood does not always increase with the duration of the diabetes.—Lymphoblastic Erythrodermia, by James H. Sequeira and Philip N. Panton. An account is given of five cases of a peculiar skin affection characterised by erythrodermia and a specific change in the blood. The blood picture usually shows a secondary anæmia, which may be severe, but the characteristic alteration consists in a relative and absolute increase of the lymphocytes. The authors would for the present place the cases in a special category distinguished on the one hand from other states of erythrodermia, and on the other from leukæmia. The appearances of the skin are shown in two coloured plates.—Changes in the Blood in Anæsthesia, by Dorothy G. E. Potter. It was noted that a fall in the alkaline reserve occurs during the first few minutes of the administration of chloroform and ether anæsthesia. A rise in blood phosphate is also frequently seen, which may be due to the passage of a hexose phosphoric acid compound from the muscles to the blood. It is suggested that the phosphate is mobilised and stored in the liver to assist in the excretion of acid by the kidneys.—The Tolerance of the Body for Urea in Health and Disease, by H. E. Archer and G. D. Robb. The authors describe an interesting series of observations upon the tolerance of the body for urea, which is analogous in some respects to the glucose-tolerance test. The resting blood-urea is first estimated, and observations are made at intervals after drinking

15 g. of urea in water, as in the urea-concentration test. In normal individuals there occurs a rise of 5 to 15 mg. urea per 100 c.cm. blood in 30 to 60 minutes, and the fall to normal is complete in 120 minutes. In renal disease, if the blood-urea is raised and the concentration is also poor, a tolerance test is not required to demonstrate renal inefficiency. In doubtful cases the resting blood-urea is often normal, and the urea-concentration test shows no deficiency. In such instances the urea-tolerance test was found of value, as deficient tolerance was indicated by an excessive rise of over 15 mg., and recovery was not complete in four hours. It is possible that the urea-tolerance test will only show deficiency in the azotæmic type of nephritis.—Calcium and Magnesium in Some Pathological Sera, by Elsie Watchorn. A series of estimations are recorded of the serum calcium and magnesium content. No definite relationship was found to exist between the variations of the two substances in certain diseased states. The calcium content was increased in some and the magnesium in nearly all of the pathological conditions investigated.—The Relationship of Infection to Diabetic Coma, by George Graham. Since the introduction of insulin patients in diabetic coma usually recover consciousness if treated suitably, but despite this death often occurs in a few days. A series of seven cases of diabetic coma are described, in all of which an infection was present. In five of them coma developed before there were any signs of the infection, which, however, became manifest during the insulin administration. It is recognised that insulin is much less effective in lowering the blood-sugar in the presence of an infection, and the possible hypotheses to explain this phenomenon are discussed.—The Spinal Fluid in Encephalitis, by James L. Halliday. Estimations made upon cases of epidemic encephalitis showed a normal fasting blood and spinal fluid sugar content. The spinal fluid sugar was found to rise after a meal, and disregard of the time relationship between the ingestion of food and the examination of the fluid may account for the high sugar content found by many workers on encephalitis and other conditions. In three cases of encephalitis samples of fluid were removed at half-hourly intervals after the administration of 50 g. of glucose. A delayed spinal fluid curve was noted in association with the blood-sugar curve.—Pituitary Obesity in Adolescence, by H. Gardiner-Hill, I. Jones, and J. Forrest Smith. A series of 60 cases is described in which the onset of adolescent obesity was associated with a period of accelerated growth. The various clinical and laboratory methods for the detection of pituitary lesions were carried out, and it was concluded that an early stage of hyperpituitarism finally passes into one of hypopituitarism. Two plates are included, illustrating certain clinical and X ray appearances.—Carbohydrate Tolerance in Myxœdema, by H. Gardiner-Hill, P. C. Brett, and J. Forrest Smith. The sugar tolerance was determined in 15 cases of myxœdema. The fasting level was usually within normal limits, but the blood-sugar curve was higher and more prolonged than in normal persons. As glycosuria rarely occurred, it is suggested that the renal threshold is raised. The general effect of treatment by thyroid extract is to lower and quicken the blood-sugar curve.

PROTOZOOLOGY is the title of a new journal published by the Institute of Agricultural Parasitology of the London School of Hygiene and Tropical Medicine, and is intended to provide a medium for the publication of new work on matters protozoological done at the Institute. The first number, which has just appeared, contains an article by Dr. J. G. Thomson on a species of giardia found parasitic in a helminth parasite of a rodent; an account by Miss M. Triffitt of a sporozoan parasite of sheep in Britain; and a description by the same author of several species of coccidia found in reptiles which have died in the Zoological Gardens. The new periodical will be issued as a supplement to the *Journal of Helminthology*.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

EVIDENCE OF THE BRITISH MEDICAL ASSOCIATION

(continued from p. 1186).

Treatment by Assistants.

(Q. 14736–40.) The number of practices in which assistants are employed is small and the Association has no evidence of insured persons being turned over by the principal to his assistant. Dr. Dain said :—

(Q. 14738.) In the practices with which I am familiar where assistants are employed, the head of the firm and the assistant work equally together. They take consulting hours at the same time and the patient probably goes into the same waiting-room and can choose which doctor she will. It is possible that she may have three doctors working all simultaneously and she goes to see which she likes. She may have the choice of three doctors, being on the panel, although only one of the doctors in such a case might be a panel practitioner.

In one large insurance practice the majority of the patients preferred to see the assistant.

Records.

(Q. 14756–9.) Dr. Brackenbury pointed out that their evidence with regard to the possible uses of the clinical records was to the effect that they might be made of great service in relation to medical research and public health. He agreed, in reply to Sir Humphry Rolleston, that it was difficult to express a considered opinion of the value of these record cards introduced so recently as 1921, but there was a feeling that more use might have been made of them, especially in relation to the public health, and that insurance practitioners generally would like to feel that more was done in this direction.

Hospital Patients.

(Q. 14794.) Dr. Brackenbury refuted the suggestion that panel patients were referred to hospitals as soon as they became troublesome. There was a good deal of misunderstanding in this matter. Patients were frequently referred to hospitals when requiring specialist treatment, and also when their home conditions did not permit of proper nursing. The hospitals had been asked by the British Medical Association to send back to the insurance practitioner cases that fell within his province, and could be equally well treated by him at home as in the hospital, and the hospitals very largely do this.

Dr. Bolam said that it was a general practice now on the part of the larger hospitals to insist that all work which is properly the work of an insurance or general practitioner should not be continuously sent to a hospital.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6); Evidence of the British Medical Association (June 6th, pp. 1184–6).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

An Income Limit for all Insured Persons.

(Q. 14843-14971.) The Association's proposals include a suggestion that many persons not at present entitled to medical benefit should be brought within the scheme—e.g., dependants of insured persons below a certain income limit and persons at present receiving medical attention under the Poor-law, and that others at present insured should be excluded by the application of an income limit to all workers, manual and otherwise. To facilitate discussion the witnesses indicated £2 10s. a week—£130 a year—as a suitable limit of income below which the dependants of the insured persons might be treated, but they did not in the least wish to be regarded as tied to this figure. The reply to the suggestion that the doctors were really not concerned with the income limit was that the doctors (Q. 14864) have accepted the National Health Insurance scheme, which is so much opposed to their traditions and ways of practice, in order to meet an acknowledged want, and they did not want to see it unduly extended. Dr. Cox said :—

> (Q. 14869.) I think the average doctor would say that the ideal form of medical practice is where the patient can go to the doctor of his choice with his own money in his pocket, and pay for it, the transaction being just between the two . . . . But we know there are people who cannot do it, and you have to provide for them. We do not want, however, to provide for any more of them under a system where the State comes in than we can possibly help.

It was agreed that in regard to manual workers, so many of whom would be in and out of benefit, an income limit would be very difficult to apply, but Dr. Brackenbury suggested that these difficulties should not be insuperable.

It appeared to emerge from the questions on the subject that the title of a person in insurance could only be settled on a record of his past earnings, with the unfortunate result that he would be insured and receiving medical benefit when his income was high and out of benefit when his income was low.

Extension and Coördination of Medical Services.

(Q. 14972–999.) It was the view of the profession that while the numbers of insured persons should be suitably restricted, the provision itself should be as far as possible complete, and that the extended service should be coördinated with the existing public services.

> (Q. 14974.) It would not be mere coördination and bringing under one local administration, but it would mean the practical abolition of some of these services by their absorption in the National Health Insurance scheme. We envisage, for instance, the Poor-law medical service and nearly, if not all, treatment centres—I use the word advisedly—as being no longer necessary if the alternative provision under the scheme were made for the people in that other way. So that it would not be a continued existence in their present form, coördinated, of these services ; some of these things would be largely, if not entirely, unnecessary.

With regard to the finance of the extended scheme, Dr. Brackenbury said they claimed that the total national cost would not be much greater than at present.

> (Q. 14976.) We are of opinion that if you take the income of all these different services there would be sufficient income in total to satisfy the whole scheme, except, perhaps, for the bringing in of the new body of dependants. Even the extra cost of bringing in the new body of dependants would have to be discounted in so far as you could thereby abolish the need of treatment clinics under the school or other authorities for those dependants. The total income of money spent upon the public health would be almost, if not quite, enough, I think—as most of us think—to finance such a scheme as we have in mind.

(Q. 14997.) If financial conditions required that a development should proceed by stages, the opinion of a majority of the profession was that extension of the scope of the service should take priority over the inclusion of dependants.

Consultant and Specialist Services.

(Q. 15000–15010.) Dr. Brackenbury emphasised the professional objections to the administration of treatment benefits in any form by approved societies. He also indicated that the various additional services suggested should, with certain exceptions, be available only on the recommendation of the general practitioner, these exceptions being the prescribing of drugs and appliances and extra services by the consultant ; and dental treatment.

In the case of dental treatment, an insured person should be able to go direct to the dentist in an emergency. Dental and ophthalmic treatment are merely individual forms of specialist and consultant treatment. As regards all specialist and consultant treatment, the witnesses had no doubt about the necessary supply of doctors being available.

In regard to tuberculosis and venereal disease it was recognised that for some time to come a salaried service was inevitable, but with the progress of medical education the time would relatively soon come when the general practitioner would be able to undertake the medical treatment of these cases with the consultant's services at his disposal in time of difficulty.

Maternity Work.

(Q. 15011–55.) With regard to the proposed inclusion of a scheme for maternity services within the insurance doctor's contract, the question was raised as to how far the increase in maternity fees now charged by doctors was attributable to the increase in the cash benefit to the insured person. The witnesses said that the increase in the fees had no reference at all to this fact, that it was common to insured and private practice alike, and that it was attributable to a variety of causes, not the least important of which was the increasing tendency to call in the doctor's services in difficult cases only.

In the extended service which was proposed, it was made clear that individual doctors should be allowed to exercise the option not to undertake maternity work, which was often that part of a doctor's practice which he would like to give up first, as it involved so great a tie.

(Q. 15088.) Dr. Dain pointed out that in the scheme which they had put in evidence they were offering the insured woman not a choice of the doctors on the panel, but any doctor willing to undertake maternity cases, non-panel as well as panel doctors. Dr. Brackenbury said :—

> We are prepared to guarantee . . . that in every case there shall be a maternity service of doctors in the same way as there is a medical service. I think if the situation was put to the doctors there would be no need for compulsion. They would arrange amongst themselves that there should be such a service for insured persons. I do not doubt it for a moment. I should not mind any legislative power being given to see that there was such a service.

Prescribed Appliances.

(Q. 15061.) The supply of appliances for insured persons was unduly restricted, and this tended to some extent to hamper the doctor in his insurance work. All the appliances that can be described as necessities should be available to the insured person under the doctor's prescription out of the Insurance Fund.

> With regard to trusses particularly and elastic stockings we should regard those as necessities rather than luxuries for the treatment of the patient. We think they ought to be available. It hampers us not to be able to secure them without considerable work and trouble.

Approved Societies' Surpluses.

(Q. 15092–15117.) It was the view of the Association that all treatment benefits should be removed from the control of societies. With regard to the contention that the funds available for these benefits belonged to certain societies, Dr. Brackenbury said that the huge accumulations which were now becoming evident could not have been anticipated by Parliament, and that in so far as they could be attributed to the segregation of good lives into particular societies, this hardly came under the head of good administration giving the societies any real claim to the funds.

Ophthalmic Treatment.

(Q. 15145–55.) Mr. Bishop Harman said that it was important that ophthalmic treatment should include proper medical diagnosis.

> The eyes are the one place where you can look into a man's body and see his nerves and blood-vessels and tissues just as though you put your head through the window and looked at this Royal Commission. . . . There are more diagnoses of serious conditions made by the ophthalmic examiner than perhaps by any other specialist.

Dr. Bolam added :—

> I have had three instances come to my own knowledge within the last month where spectacles have been supplied by opticians in good faith, the patient going in good faith to the optician. A visit to an ophthalmic surgeon in one case led the surgeon to infer from the eye condition that the patient was suffering from diabetes, and this was found to be the case ; in a second, the patient was found to be suffering from Bright's disease ; and in the third the condition was found to be due to syphilitic disease of the eye. That is just within one man's experience.

Payment by Attendance.

(Q. 15157–15212.) Dr. Stanley Hodgson explained the system of payment in force in Manchester and Salford. The amount available for the area as a whole is the same as under the capitation system of payment, but the doctors are paid by reference to the number of attendances, visits, and special services instead of according to the number of persons on their lists. The bills of doctors who have made apparently an excessive number of attendances are scaled down by reference to the general average, and the bills as a whole have then to be scaled down within the limits of the total sum of money available. He did not think there was much in the suggestion that under the attendance system the insured person felt less compunction in making visits to the doctor, as he doubted whether insured persons were sufficiently aware of the facts.

(To be continued.)

Reports and Analytical Records.

GAYMER'S CIDERS.

(MANUFACTURED BY MESSRS. WM. GAYMER AND SON, LTD., ATTLEBOROUGH, NORFOLK. LONDON OFFICES AND STORES, 521–529, HACKNEY-ROAD, E. 2.)

THE undermentioned ciders have been sent to us for examination :—

1. *Sparkling Pommetta.*—A cider of a dry variety produced in the champagne style and made from a special blending of apples in order to obtain a particular character and bouquet.

2, 3. *O.N.S. and N.*—Two dry ciders.

4. *V.D.*—A dry cider ; although not quite so dry as samples 2 and 3. This cider is claimed to possess a special character and bouquet of its own.

5. *Two Star.*—This cider is similar in quality to the V.D. brand, but is slightly sweeter.

6. *Diamond.*—A sweet cider.

When these different brands were analysed the following results were obtained :—

Number.	Specific gravity before fermentation.	Present specific gravity.	Total solids, per cent.	Alcohol, per cent. by volume.	Invert sugar, per cent.	Acetic acid, per cent.	Malic acid, per cent.	Flavour.
1	1061·9	1018·7	6·87	5·55	4·52	0·07	0·78	Full flavour, good palate ; not very sweet.
2	1058·6	1016·7	6·31	5·4	4·26	0·02	0·64	Full palate, rather dry.
3	1051·6	1018·5	6·35	4·25	4·53	0·07	0·67	Very dry, fine palate.
4	1055·7	1020·6	7·0	4·55	4·82	0·05	0·64	Fairly dry, good flavour.
5	1052·9	1025·6	7·9	3·55	6·16	0·10	0·56	Good palate, sweeter than No. 4.
6	1051·0	1030·2	8·86	2·57	7·64	0·04	0·45	Full sweet flavour.

Preservatives : Benzoates, salicylates, and naphthol were absent in each specimen examined.

These ciders, judged from their bouquet, flavour, brilliancy, good condition, and analyses, are very satisfactory ; moreover they are well and carefully bottled and attractively labelled. All are of a good gravity and obviously quite free from any impurity. Samples 2, 3, and 4 are recommended as a beverage to those who suffer from gout, rheumatism, and kindred disorders.

LIPOIODINE CIBA.

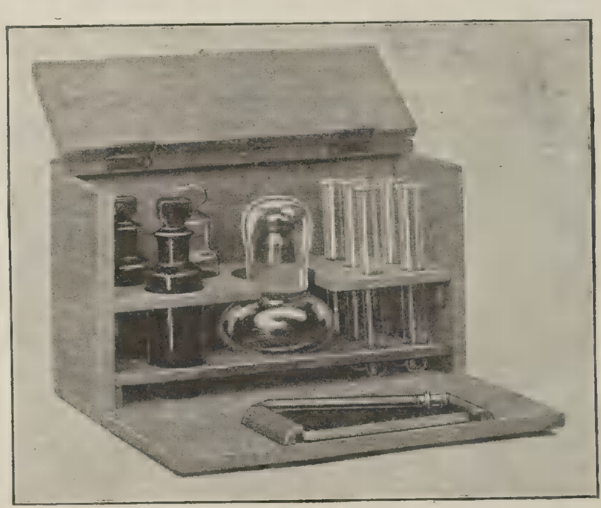
(CLAYTON ANILINE COMPANY, LIMITED, 68½, UPPER THAMES-STREET, E.C. 4.)

This is a preparation which has been widely recommended as a pleasant method of administering iodine without producing symptoms of iodism. The drug is the ethyl ester of di-iodobrassidic acid, containing over 40 per cent. of iodine, and its pharmacological properties are those indicated by its composition, while the drawbacks to the administration of the alkaline iodides are avoided. And all can look back on the disagreeable results of the wrong exhibition of potassium iodide. Medical testimony from sound sources speaks of the stability of lipoiodine "Ciba" and of the slowness of absorption and elimination which allows of prolonged and well-watched treatment. The specimen sent to us for examination is a small case of 20 tablets each containing 5 gr., and a tablet can be taken three times daily, but, as the proprietors are careful to say, only in accordance with the directions of a physician.

New Inventions.

A PATIENT'S URINE-TESTING OUTFIT.

I HAVE designed the little outfit herewith illustrated for the use of diabetic patients who are on dietetic or insulin treatment. Everyone recognises the advantages of patients examining their own urine regularly. The result of any indiscretion is at once apparent and they are much more likely to adhere to the prescribed diet. It also enables intelligent patients to regulate their dosage of insulin. The outfit consists of Fehling's solution No. 1 and No. 2, liq. ferri perchlor. dil., a spirit lamp, half a dozen test-tubes, a notebook to record daily results, while full directions for the test are printed on the lid. The whole is enclosed in a neat wooden case. I recommend Fehling's instead of Benedict's test as all medical men are familiar with the former and can better assist the patient if he gets into difficulties. I think it is essential that patients should test occasionally for diacetic acid and should be instructed to get medical advice at once if any red coloration is shown with the ferri perchlor.



The outfit has been made by Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, W. 1.

THEORY & PRACTICE

THAT the 'Allenburys' System of Infant Feeding is sound in theory is evinced in the light of the accumulated knowledge of dietetics ; that it is right in practice from the extent to which it has been used and the satisfactory results of actual experience over a period extending for several generations.

The necessity of including in the dietary of infants, fresh elements which are relatively rich in vitamins has continually been emphasized by us. The daily use of accessory foods such as orange juice and Cod-Liver Oil is an integral part of the 'Allenburys' System of Infant Feeding. For over 20 years the use of such elements has been recommended in our literature and included in the printed directions on the label of each tin of 'Allenburys' Foods.

If you have not received our new publication, "The 'Allenburys' Foods in Infant Feeding," or have mislaid your copy, we shall be glad of the opportunity of sending you another.

THE LANCET.

LONDON: SATURDAY, JUNE 13, 1925.

THE ADVANCE OF THE GENERAL PRACTITIONER.

The visit of the Inter-State Post-Graduate Assembly of America to London, which concluded last week, was in effect a movement on the part of a group of Canadian and American general practitioners to equip themselves to the utmost for their work in general practice. Time after time in lectures and addresses given during the visit—as will be seen in our reports of the proceedings—reference was made to the function of the practitioner of medicine in the community. At the Guildhall banquet Dr. Charles Mayo, who presided, said, in so many words, that where the general practitioner does his duty the reputation of medicine will stand high in that community; and our American visitors themselves showed an almost amazing addiction to duty in attending during a period of peerless weather morning lectures and afternoon demonstrations of various kinds; but it was revealed amusingly at the banquet that the congressists had gone into training in preparation for the visit, for 65 medical addresses were delivered on the boat on which most of them came over. Dr. Mayo went on to speak of the great need for graduate schools of medicine, and coming from one of a team of brothers who have built up a school of teaching whose influence has irradiated widely from its centre of origin, his words carry great weight. He spoke appreciatively of the facilities offered to American delegates during the present visit, but delivered his real message in the advocacy of founding in London a graduate school of medicine which should draw students from all quarters of the English-speaking world. To his mind such a school should be run by men of distinction and achievement who, after laying down their hospital appointments, preferred to devote their advancing years to teaching others rather than to rust out in rural comfort—Dr. Mayo and his colleagues evidently all share the conviction that prolongation of mental activity also prolongs physical life.

Such a scheme has been advanced by Mr. Philip Franklin, whom Dr. Mayo described as one of the best organisers in medicine, and should it be found feasible medicine might be enabled to play a larger rôle in the life of the community. Mr. Neville Chamberlain, the Minister of Health, with no deliberate intention of supporting any particular movement, showed himself in favour of such a scheme. For he reverted constantly to the function of the general practitioner as the educator of the community in health, and first and foremost in the principles of preventive medicine; but while medicine has for long envisaged this as an ideal, the difficulties, if not insurmountable, are still to be surmounted. It is true that in the region of public health administration the application by enlightened authorities of powers already existing would do away largely with the need for new legislation, and equally true that application of the results of modern scientific discovery, if they could be applied, would at once raise the level of practice to an incredible extent. But the latent period is lengthy and is being reduced too slowly. Laboratory research takes long enough to reach the popular text-book of physiology or medicine, and still longer to get into the hands of the practitioner, who then has to assimilate the teaching, and, may be, to translate the findings into a form which can be appreciated by his public. And where hygienic knowledge is present, the will to apply that knowledge may be dormant or even completely absent. The visit of several hundred keen and thoughtful general practitioners of both sexes to this country, using the English language as the common bond with us and between themselves, will have its repercussion in stimulating the scientific practice of medicine in this country. We on this side are less able to cut free from the daily round, or to find the necessary money to make the medical tours which our American colleagues can accomplish; but certainly, as a result of this entente, more of us will find time and means to cross the Atlantic in search of wisdom on the other side. In the meantime, the great need for graduate schools at home is becoming too apparent.

◆

FERTILITY OF THE POPULATION OF ENGLAND AND WALES IN 1921.

The volume just issued by the Census authorities[1] tabulates the answers to two questions of the Census Schedule of 1921 which were novelties. One question required a statement in respect of each person under 15 enumerated on the schedule as to whether either of his or her parents were alive or dead. The other question invited all married men, widowers, and widows to return the total numbers and several ages of their children and step-children alive and under the age of 16 at the date of the Census, whether such children were enumerated with their parents or not. The primary object of these questions was economic—viz., to obtain data for estimates of the cost of State liabilities such as pensions, invalidity allowances, workmen's compensation, &c., but the results throw some light upon other sociological phenomena. The second of the questions mentioned is particularly interesting, and the way in which it was answered adds another to the many previous illustrations of the essentially limited scope of useful census-taking. In a large proportion of cases the question was not answered. Of 7,475,051 married men, 1,030,661 did not state the number of children. Many of the failures to answer the question really meant that the recorder had "no living children under 16," but an absolutely large number of omissions to give positive information certainly remains. The number of children under 16 obtained by answers to this question was about 8 per cent. less than the total enumerated. The actual error in defect is not, of course, so vast as this difference suggests. The question did not cover illegitimate children of unmarried persons, the children of married men abroad at the time of the Census, or orphans with both parents dead. In this way probably a difference of as much as 5 per cent. might arise, so that the actual deficit is likely to be not more than 3 per cent.

The fact remains, however, that a question, somewhat complex, judged by past Census standards, but extremely simple in comparison with those pressed by enthusiastic amateurs whenever a Census is under discussion, was not very satisfactorily answered. It is too much to expect the various enthusiasts who clamour for national stocktakings of this or that character of, as they claim, racial importance to read the reports of our Censuses ; but level-headed persons before supporting any of the proposals of enthusiasts or condemning the conservatism of bureaucrats should certainly do so. The inquiry, as will have been seen, had no express relation to the subject of nuptial fertility, but there was a necessary connexion because the statistics enabled the following ratio to be calculated : Number of children under 1 year of age *divided by* total number of married men (or married women). This ratio could be computed for geographical and (for married men) occupational subdivisions. This measure is, of course, different from the ordinarily employed fraction : Number of children born in a year *divided by* average number of married men (or women) exposed to risk during the year. One cannot be converted into the other by a constant multiplier because of variations of both infant and adult mortality. But, nevertheless, the two ratios are highly correlated, and a rate of fertility deemed high (or low) by the use of one ratio would still be classed as high (or low) if the other index could have been calculated. There is also a source of error—viz., that these data include step-children, so that one may find, and does find, some infants credited to parents outside the normal range of fertile ages. In spite of these defects, the compilers are, we think, justified in holding that the tables "with liberal and intelligent treatment" provide an interesting study of the incidence of fertility among various sections of the population during the year preceding the 1921 Census. We cannot, of course, discuss the details of this tabulation, which will, no doubt, be examined in the final report. A few points may, however, be noted. The contrast between the mining districts of the country and other parts in respect of fertility is very obvious. Using the ratio of children under 1 to married men of all ages as the standard, and putting the ratio for England and Wales as 100, the figure for Durham is 134, for Northumberland 116, for Monmouth 128, for Glamorgan 121. On the other hand, the figure for Sussex is 79, for Devon and for Surrey 82, for Dorset 88. An occupational comparison brings out the same contrast. The figure for mining and quarrying occupations is 150, for agricultural occupations 90, for textile workers 83, and for professional occupations 66.

---

[1] Census of England and Wales. 1921. Dependency, Orphanhood, and Fertility. London: H.M. Stationery Office. 1925. Pp. 253. £1 10s.

No tabulation of vital statistics can fail to show the consequences of the war, and the table of the orphanhood of children under 15 is a case in point. If one works out the percentages of children aged 1, 2, &c. (boys), whose mothers were dead at the Census date, the percentages are as follows : Boys, aged 1, 0·64 per cent. ; aged 2, 1·25 per cent. ; aged 3, 1·69 per cent. ; aged 4, 1·97 per cent. ; aged 5, 2·24 per cent. ; aged 6, 2·58 per cent. ; aged 7, 2·95 per cent. ; aged 8, 3·24 per cent. ; aged 9, 3·66 per cent. ; and aged 10, 3·92 per cent. Plotted on a chart these percentages increase smoothly, a straight line joining the first and last runs near all of them. The percentages of fatherless boys are different. They are 1·62, 3·55, 4·66, 5·88, 6·89, 8·06, 8·56, 8·77, 9·17, and 9·64. If these are plotted and the first and last joined, the points lie on a bent bow of which the line is the string. The points diverge more and more from the line to a maximum distance for the children aged 6, and then pass back towards the line. The principal factor of this difference is, of course, the destruction of life in the war. Between 3·5 per cent. and 8·6 per cent. of all children born during the war are fatherless, and from 1·25 per cent. to 3 per cent. are motherless.

◆

GASTRIC CANCER AND GASTRIC ULCER.

CONFLICTING evidence renders it very difficult to decide what part, if any, a simple gastric ulcer takes in the genesis of carcinoma of the stomach. The subject came up for some consideration during the American post-graduate visit to London. Mr. JAMES SHERREN, in a short address reproduced on p. 1266, stated that he had never seen carcinoma develop after gastro-jejunostomy for a small mobile ulcer on the lesser curvature, although it was none the less true that in at least a quarter of cancerous stomachs evidence of preceding simple ulcer could be found. Dr. CHARLES MAYO, at the Surgical Section of the Royal Society of Medicine, also remarked on the rarity of cancerous degeneration in small ulcers. The question is of much more than academic interest. It is of very great practical importance to the operating surgeon. Should he hold the belief that gastric ulcer is a material factor favouring the development of malignant disease, he must, logically, incline to excision in all cases where it is technically possible, for the alternative treatment of gastro-jejunostomy is not claimed to be invariably successful in promoting cicatrisation even by its staunchest advocates. An interesting contribution to the subject has recently been published by Prof. J. H. DIBLE.[1] He gives the results of an inquiry instituted by the Manchester Pathological Society. The material used was chiefly specimens removed at operations in the Manchester and Salford Hospitals. Of those 126 cases in which the clinical and naked-eye appearances pointed to simple ulcer, the histological evidence confirmed the diagnosis without a single exception. He points out, what other pathologists have drawn attention to, that near the edge of an ulcer down-growths of epithelium can be found which are not evidence of malignant disease though they are apt to be interpreted as such. They were found in 32 per cent. of the series under discussion and seem to be the result of the distortion of the tissues which takes place in the process of healing. In 23 cases diagnosed clinically as carcinoma and excised, and in which the lesions were at a sufficiently early stage to afford results capable of interpretation, in 19 no evidence was found in any way suggestive of pre-existing ulceration, and in 9 the weight of evidence was against any causal associations of chronic ulcer with carcinoma. There were five cases in which, on histological grounds alone, the appearances might be taken to mean that malignant disease had been grafted upon a chronic ulcer. The author also points out that the site where cancer is most frequently seen, that is, in the vicinity of the pylorus, is not the most common site for chronic ulcer, which, in 73 per cent. of cases, is the lesser curvature. His conclusion is that transformation of a chronic gastric ulcer into a carcinoma is a possible but rare occurrence.

In contrast with that view is the recently expressed opinion of H. FINSTERER.[2] In 175 resected callous ulcers of the stomach, 27 per cent. showed malignant degeneration, contrary to the experience of the Manchester surgeons. He says that it may be impossible to tell clinically, by X rays, or on the operating table, whether an ulcer is malignant or not. In

---

[1] Brit. Jour. Surg., 1925, xii., 666.

[2] Wien. Klin. Woch., 1925, xxxviii., 295 and 321.

145 gastric resections there were 31 carcinomas, where all the available evidence, until a histological examination had been made, pointed to the lesion being a simple one. The case-histories of five recent cases are given, and in two of these a Haudek's diverticulum on the lesser curvature was demonstrated early in the disease. It would seem that it is very easy to overlook the degenerating area of a chronic ulcer unless a searching microscopic examination is made. The end-results when such ulcers are excised, under the mistaken belief that they are simple, are disappointing. Local recurrence is not common, but in the majority of cases death occurs from metastases in the liver or retro-peritoneal glands. FINSTERER says that it is easier to recognise beginning malignant degeneration in a simple ulcer by a change in the clinical symptoms, than to be certain of it on the operation table. From his extended experience he strongly adheres to the view that wide resection in simple gastric ulcer is to be regarded as a procedure prophylactic against future malignant disease. There is thus at the present time a frank divergence of view between surgeons of distinction on the best method of saving the patient's health and life in this common malady. It is essentially a matter which only a further collection of pathological evidence will decide.

MODERN TECHNIQUE.

IN the manifold duties asked of the family doctor effective treatment of any and every ailment takes the first place. That is all that is asked, for the most part, by those who have no conception of the size of the demand. The careful elucidation of the nature of the disease, necessarily of paramount importance in the medical schools, is less appreciated in practice than the palliation of symptoms, though every logical method for healing must be based upon an accurate nosology. Those in practice often require help most urgently in situations where recent developments of medicine or surgery have led to practical therapeutics whose virtues are open to proof. When in January, 1923, a series of articles entitled "Modern Technique in Treatment" were initiated in THE LANCET, the welcome given to them by our readers was cordial to a point which we had hardly dared to expect. Their reissue as books was not contemplated, but many practitioners throughout the country have urged that the series could usefully be reprinted in handy volumes, and accordingly the contributions to the series which had appeared during the first year and a half of publication have been collected together and issued in book form on June 10th. The 76 chapters in the first volume cover a wide range of subjects. Some deal with well-defined diseases and suggest a specific curative agent; others treating of symptoms common to many conditions—such as toothache, constipation, or hæmorrhage from various sources—recommend the palliative treatment which is called for pending the investigation of the underlying condition.

The demand for this first volume encourages us to continue to devote space in THE LANCET to these articles, and publication of them in collected form will be made from time to time. It is our hope thus to set out in a handy manner a balanced and representative statement of the treatment at present advised, and, especially, to stimulate workers both in academic and applied branches of therapeutics to examine and record any promising methods for trial under controlled conditions.

Annotations.

"Ne quid nimis."

ACCIDENTAL STRYCHNINE POISONING.

AT a recent inquest on a child, aged 11, who died from the effects of strychnine poisoning, it was stated that the nurse accidentally gave 4 drachms of the medicine instead of four drops—that is, roughly, 60 times the quantity prescribed. In this country, fortunately, accidental deaths from strychnine poisoning are very few. The Registrar-General's return for 1921 and 1923 gives the number as five and three respectively for all ages, whilst the total deaths from strychnine poisoning and for all ages are 20 for each of the two years quoted. In the majority of cases the source of the strychnine is not stated, so that it is impossible to say how far medicines and how far vermin-killers are responsible. It is, of course, possible that the total numbers may be slightly in excess of these figures, as it is likely that some cases are not recognised; but in any case it may be safely assumed that the total is not much above 25 per year. Further, in the two years quoted 15 cases in each year were due to suicide. Additional restrictive legislation has from time to time been advocated, but from these figures it seems hardly necessary. In America, however, a very different state of affairs exists, for out of 70 deaths from accidental poisoning during 1924 among children between 1 and 4 years of age, insured in the Industrial Department of the Metropolitan Life Insurance Company of New York, strychnine compounds accounted for 24. In the majority of cases cathartic pills left within the reach of the child were the occasion of poisoning. In other cases tonics (presumably prescribed for adults) were taken with fatal results by the child. The fatal cases were scattered over the whole of the United States and Canada, and the *Statistical Bulletin* of the company comments that evidently the danger of strychnine compounds is not generally appreciated. Such highly poisonous drugs, the *Bulletin* suggests, should be procurable only on a physician's prescription. Roughly speaking, the population of England and Wales is about one-third of that of Canada and America combined, but even when allowance is made for the relative populations the difference is striking. It would be interesting to learn the ratio between the deaths of insured and of uninsured children, for the insurance factor may be the important one. Should the relatives of the child benefit financially at its death, the explanation of a certain amount of laxity may be found in countries where no legislative restriction has been imposed.

THE SPECIAL VULNERABILITY OF THE MACULAR FIBRES.

THE special vulnerability of the macular fibres and "sparing of the macula" is the subject of a suggestive paper contributed by H. M. Traquair to the *British Journal of Ophthalmology* for February, 1925. Though certain forms of disease of the central visual elements appear to support the hypothesis of special vulnerability, the author says that "when we examine the evidence closely it becomes clear that while the central elements as a whole are easily affected it is by no means always those whose physiological function is most highly elaborated which suffer soonest or most severely." Thus the scotoma of toxic amblyopia begins, as a rule, as a paracentral rather than as a central defect, and in recovery from retrobulbar neuritis a rapid access of central vision may occur while there is still a ring scotoma. With regard to the vexed question of "sparing the macula" in hemianopic affections, he claims that only in wounds in which actual destruction by trauma of the macular cortical centre or its fibres can take place is division of the fixation area at all common. In certain vascular lesions, however, the macular area may be divided, and in the case of tumours which gradually compress the radiations the fixation area may be spared at first and divided later. The functional superiority of the macular neurones suggests that a greater degree of interference may be required to put them out of action, whether it is caused by vascular disease or by pressure on the radiation by a tumour.

The subject is one concerning which it would be unwise to dogmatise, and it is complicated by the fact that there are still differences of opinion about the projection of the retina on to the cortex of the brain. Dr. B. Brouwer, of Amsterdam, in a recent lecture, arranged by the University of London, related experiments on certain monkeys, demonstrating that the projection of the macular fibres in the geniculate body occupies a large portion of that structure. If a corresponding diffusion of macular fibres is found to take place in the occipital cortex it will be a factor which must be taken into account.

FIFTY YEARS' PUBLIC HEALTH WORK IN ARGENTINE.

It is not often that a medical man is invited by a learned society to recount the story of his life, but one who has organised and maintained a public health service in a country for over 50 years has justly something to his credit of which he may be proud to talk, and in April last Dr. Emile R. Coni presented a report of his activities before the Academy of Medicine in Paris. Dr. Coni was of French ancestry, and he tells how, during his student days in the hospitals at Buenos Aires, he was appalled at the conditions then existing. Suppuration abounded, the wards were in a dreadful state of dirt and disorder, tuberculous patients were relegated to damp cellars, where they died, "devoured by flies and by consumption." While still a fifth-year student he was elected as an honorary member of the only medical society then existing in Argentine and he became editor of the *Revue Médicale*, the only medical journal in the country, and in this publication he conducted an active campaign against the terrible conditions in the hospitals. When qualified he continued by means of journalistic work—for the pen was ever Dr. Coni's ready weapon—to press for some measure of reform in hygienic conditions in general, and after about 20 years of private practice he decided to devote himself body and soul to public health work. In 1880 he was able to begin to put into practice some of the measures which he had urged through the medium of the *Revue Médicale*, and he claims to have proposed the establishment of a ministry of health before this centralisation of public health activities was envisaged in Europe. In 1896 and 1897 Dr. Coni was appointed to carry out a sanitary survey of two of the Argentine provinces, Mendoza and Corrientes, and despite enormous difficulties he succeeded after many years in bringing about some centralisation of control with the establishment of efficient water-supplies, drainage systems, and complete public health services. Almost every branch of social medicine in Argentine appears to owe its foundation to the energies of this remarkable man. His first important publication, which appeared in 1879, was on infantile mortality in Buenos Aires, and in 1885 a thesis on the same subject brought him a valuable prize from the Faculty of Medicine of that city and the silver medal of the Academy of Medicine of Paris. He founded child welfare work, organised a system of school medicine, and eventually succeeded in obtaining instruction in infant welfare for girls in nearly every educational establishment in the country. The state of maternity work in Buenos Aires when Dr. Coni first turned his attention to it was appalling to the last degree, but at the present day, thanks to his untiring efforts, the town can boast six municipal and two national maternity homes. Campaigns in Argentine against tuberculosis, alcohol, venereal disease, leprosy, and even tobacco have all received much of their initial stimulus from Dr. Coni. His titles and distinctions would occupy a page; as a statistician he has set the study of disease in his country on a scientific basis; his publications, both in French and in the language of his adopted country, would fill many volumes; he has taken an active part in the municipal work of Buenos Aires, and he is acknowledged throughout Latin America as a brilliant pioneer in the field of public health. At last, broken in health and almost poverty-stricken, Dr. Coni was granted a pension by the Argentine Government, and he returned once again to France to give an account of his manifold activities before the Academy of which he had been a member for over 25 years.

AN OUTBREAK OF FOOD POISONING AT PLYMOUTH.

Dr. A. T. Nankivell, medical officer of health, Plymouth, has recently reported to the Plymouth Guardians upon an extensive outbreak of food poisoning which occurred amongst the inmates and patients at the workhouse and infirmary on April 30th. Out of a total of 730 persons no less than 308 were attacked, while, in addition, there were cases which did not report sick. The symptoms were those of gastro-enteritis of varying severity. There were no deaths, and all the patients were practically well within 24 hours of the onset of symptoms. The incubation period is not given definitely, but as the peccant meal was the midday dinner, and the symptoms came on during the same evening, it was obviously only a few hours. Owing to the fact that nine women engaged as charwomen, who resided outside the institution, were all attacked in their own homes, and their only meal in the institution was the midday dinner, it is possible to incriminate this meal with certainty. This meal consisted of beef, potatoes cooked under the beef, mince, gravy, cabbage, bread pudding, sago pudding, and milk. The beef itself was not the cause, since the rest of it was traced, while those portions not cooked by the kitchen staff of the main workhouse and eaten by 64 of the staff caused no illness. Dr. E. Wordley, the Plymouth borough pathologist, examined samples of all the food bacteriologically and found no food poisoning bacilli. He also failed to find these organisms in the fresh fæces of 12 patients or in the vomit of another patient. Blood from sufferers ten days after the attack were all negative.

The clinical and bacteriological findings suggest that the outbreak was not due to a living bacillary infection, and Dr. Nankivell considers that it was due to a heat-resisting toxin of one of the Salmonella groups of organisms. To explain its origin in the food the procedure in the workhouse kitchen was carefully investigated. Food left over from one day is used on the next. The unused gravy and stock is tipped from the stock-pot into enamelled iron bowls and placed in the larder. The stock-pot is then cleansed, and on the following day the stock from the enamelled bowls is placed again in the stock-pot and re-heated. Some of it is used for putting in the pans in which the beef, and the potatoes under the beef, are roasted. The stock never dies. An infection of the stock by a food-poisoning bacillus would result in the stock in the larder containing abundance of these bacilli by next day. The re-cooking of such infected stock would kill the bacilli but leave the heat-resistant toxins undestroyed. This very reasonable hypothesis is suggested as the source of the toxins. Careful attention was directed to the kitchen staff to try and ascertain the source of the food poisoning bacillus. Apart, however, from the fact that it was ascertained with probability that the chief cook became slightly ill with diarrhœa and vomiting on April 28th and 29th, and that one of the assistants was habitually most careless about his personal hygiene, nothing very definite was forthcoming on the epidemiological side. Bacteriological samples were examined by the bacteriologist to the Ministry of Health. The blood samples from all members of the kitchen staff were negative, presumably as regards agglutination, while fæces from the kitchen staff were all negative except from the chief cook. This was found to contain "bacilli culturally resembling *B. suipestifer*, but these have shown no serological affinities with the stock *B. suipestifer*." It is suggested that this officer was the source of infection of the food. While this is a possible hypothesis it is not more than a hypothesis, and there are facts which militate against it. In particular, if this cook suffered from an infection with a living Salmonella strain sufficient to cause a definite attack of gastro-enteritis it is to be anticipated that his serum would give a positive agglutination reaction with the infecting bacillus, whereas his blood reactions were negative. While the larder was kept very clean, the possibility of contamination from dirt, dust, and flies was not excluded.

The outbreak was worked out with great care by Dr. Nankivell and his assistants, and he concludes his report with recommendations that steps should be taken to exclude dust and flies from the food, that only persons of known cleanly habits should be employed in the kitchen, and that it should be an instruction to all members of the kitchen staff to wash their hands thoroughly after defæcation and to wash their hands on coming on duty into the kitchen.

FURTHER EXPERIENCE WITH RADIUM.

IN the May issue of the *Irish Journal of Medical Science* Dr. Walter C. Stevenson writes on 174 cases treated by him with radium during the year 1925 (evidently a misprint for 1924). The cases treated naturally divide themselves into two classes, the malignant and the innocent. The technique employed in the former is to bury steel needles, and in many cases to reinforce this by the application of radium to the external surface. Dr. Stevenson is a believer in the theory that better results are obtained by placing the radium at some distance from the skin, and to obtain this end he places an empty match-box between the skin and the applicator. His ideal procedure in a case of carcinoma of the breast is to irradiate the diseased area four days before amputation and, immediately after the removal of the breast and axillary contents, to insert tubes of screened radium into the wound, thus giving a further dose to any malignant cells that have escaped both the first irradiation and the surgeon's scalpel. Apart from malignant tumours Dr. Stevenson has treated with radium such various conditions as fractures, "injuries to elbows," lumbago, toothache, colitis, acute sciatica, and tonsillitis, stating, rather surprisingly, that "to my mind it is quite rational to use radium in acute pneumonia, in the acute stage." Radium is so steadily gaining ground in the treatment of many forms of cancer and in not a few forms of non-malignant diseases that unsubstantiated claims are the more to be regretted. In the same issue of the journal Mr. Maurice R. J. Hayes gives a short but complete résumé of the modern treatment of rodent ulcers by radium; he has come to the conclusion, after a long experience of treating these conditions both by surgery and X rays, that radium is the ideal weapon to employ. His experience of carcinoma of the lip is confined to recurrent growths following operation. Those cases which were treated early, before the disease had implicated the glands, did well, but those in which the glands were already infected were not much benefited. Full details are given of a number of advanced cases of inoperable carcinoma of the uterus and cervix. All these were rapidly improved by "needling," but the difficulty he has found is in dealing satisfactorily with the glands. If a method could be devised to destroy the malignant cells in the pelvic and abdominal glands or to prevent their infection, a very great advance would have been made in the treatment of this condition. In none of Mr. Hayes's cases did a rectal or vesical fistula develop—a fact which goes to show once again that in nine cases out of ten the formation of a fistula is to be blamed, not on the radium, but on the method in which it is employed, if not on the natural progress of the disease. Mr. Hayes comes to the conclusion that the best results in carcinoma of the uterus are reached by a combination of radium and X rays; radium for those parts which are accessible, while the deeper-placed disease, such as abdominal and pelvic glands, is best treated by X rays. Further reports on his interesting scientific work will be welcome.

VOLUNTARY BOARDERS AT DARTFORD MENTAL HOSPITAL.

THE report of the visiting committee to the City of London Mental Hospital at Stone, near Dartford, for the year 1924, which has just reached us, confirms the announcement already made in these columns [1] that this institution now has the statutory right to receive voluntary boarders. The Act conferring this right has also permitted the all-important change in name from "asylum" to "mental hospital." The time is indeed more than ripe for the extension of these privileges to other public institutions in the country. Since the passing of the Bill in July last five voluntary boarders have been in residence at Stone, and their number will no doubt increase steadily. We learn, further, from the report that the principle of allowing patients out on parole has been used with much success in a large number of cases, and the way to discharge has been paved in a few instances by granting short leaves of absence up to four nights. A valuable feature in the works department at Stone during the year has been the provision of further open verandahs, attached to the wards, whereby suitable patients can be nursed entirely in the open air. An operating theatre, pathological laboratory, and X ray room are being added. An increasing number of rate-aided patients are being fitted out with clothing, made in the hospital workrooms, which is similar to that of the private patients. The resignation of the medical superintendent, Dr. R. H. Steen, after a long period of ill-health, is a cause of much regret to all who are acquainted with the valuable services he has rendered to this important institution. His successor, Dr. William Robinson, lately superintendent of Brentwood Mental Hospital, will have a valuable opportunity for contributing to the study and treatment of mental disease under modern conditions.

SIR WILLIAM BARRETT.

Sir William Barrett, whose recent death, at the age of 81, has already been reported, was one of a distinguished group of scientific men whose observation was transferred as they grew older from incidental to transcendental phenomena. Assistant to Tyndall, his early discoveries concerned sensitive flames and certain curious properties of iron alloys, while a 37 years' long occupancy of the Chair of Physics at the Royal College of Science in Dublin gave him abundant opportunity for popularising the growth of physical science. Attracted along with Russel Wallace and Crookes to the exploration of obscure human faculties, he satisfied himself of the existence of a faculty of communion or communication between individuals independent of the recognised organs of sense. Sir Oliver Lodge, who writes his memoir in *Nature* (June 6th), notes that Barrett considered that he might hereafter be regarded as perhaps the chief discoverer of this faculty. His paper read to the British Association at Glasgow in 1876 on what was later called "telepathy" did not appear in the printed proceedings, but a letter of his in *Nature* five years later paved the way for the foundation of the Society for Psychical Research. Barrett's other inquiries included the sensitiveness of certain people to magnetic fields, and the faculty possessed by some for finding water or other things by means of an unconscious physical reaction. He was the recipient of a vast correspondence from all parts of the world, recording extraordinary happenings, a selection of which appeared in the Proceedings of the Society, which had a branch of its own in Dublin. Barrett's friends could not always keep up with one whose eagerness to follow clues made companionship stimulating to the point of unrest, but fully recognised the transparent honesty and simplicity of his character and his readiness to undertake any labour to get phenomena properly observed and recorded. He was, as Sir Oliver Lodge reminds us, never deterred by ridicule or opprobrium from following such clues as he could find. Death did not seem to Barrett to be an interrupter of mental continuity, and he did not fear it.

---

[1] THE LANCET, 1924, ii., 709.

THE HYGIENE OF A TORNADO.

AT 2.28 P.M. on March 18th last a tornado travelling at the rate of 60 miles an hour along a path about a mile wide struck the town of Gorham in Illinois, and crossed five counties, remaining in contact with the ground the whole time. The population of the devastated territory numbered about 200,000, being largely rural with one or two towns of up to 10,000 or 12,000 inhabitants. Among this population the local public health service was mostly in a primitive state, and the *Illinois Health News* for May gives an account of steps taken by the State Health Department to deal with the problem. The towns of Murphysboro' and West Frankfort had public water-supplies, but in most parts of the area drinking-water was obtained from private wells and cisterns, many of the former liable to surface pollution. There was no local control over milk-supplies in the area before the tornado and the only pasteurisation plant was at West Frankfort. At Murphysboro' and West Frankfort there were public sewerage systems; otherwise privies were the rule. None of the communities had a system for the collection of refuse. Many hundreds of horses and cows and domestic animals were killed by the tornado. Many people were rendered homeless. The first news of the disaster reached Springfield at 8 P.M. on the same day, and a special train left with a rescue party on board, arriving at Murphysboro' at 2 A.M. the following morning. By the morning of the 20th the five sanitary engineers of the State Department were in the area, and within 36 hours a complete health department was functioning with headquarters at Carbondale. Medical and nursing relief to the injured was provided, the dangers of communicable diseases were met by isolation and immunisation, and sanitary measures were adopted. All the work was done in close coöperation with the military authorities, who were charged by Governor Small with the responsibilities of relief and re-habitation. The medical and nursing relief work was turned over to the Red Cross organisation on the second Sunday after the disaster. Temporary emergency work was followed by organisation on a permanent basis to handle problems which are sure to continue for a year or more. A diagnostic laboratory was established at Carbondale, while the sanitary work was extended to include control of the water-supply, the milk-supplies, and the disposal of refuse. There has always been an excessive prevalence of typhoid fever and malaria in this area, and the prevention of both these diseases received attention. During the first two weeks about 4000 persons were immunised against typhoid, and probably about 20,000 will have been inoculated before the campaign ends. In the wake of the storm there arose conditions extremely favourable to the development of epidemics, especially typhoid fever. The injured were liable to tetanus and gas gangrene. A month after the disaster no epidemics of any kind had appeared in the affected area. Only five or six deaths resulted from tetanus and gangrene among the thousands who were injured. The activity of the State Health Department in the tornado zone and the success of their operations has created a demand for a permanent local health organisation. Wells and water-supplies which were temporarily disorganised were subjected to extra chlorination; tent camps were established for the homeless; arrangements were made for the removal of refuse; carcasses of dead animals were burned and buried.

One result of the disaster will certainly be an improvement in public hygiene. In our crowded country, with a local sanitary authority in every district, it is difficult to realise the great responsibility thrown upon State departments administering huge sparsely inhabited districts in which there is practically no local health organisation. The State Department of Public Health in Illinois is to be congratulated on the promptitude exhibited in dealing with the effects of the tornado.

THE MEDICAL WHO'S WHO.

THE seventh edition of this work of reference, dated 1925, has just reached us, regret being expressed for the delay, which is attributed largely to the entire resetting and alteration in size from former editions. The last appearance of the volume was in 1918, when, owing to the death of its then editor, it fell into abeyance. In this volume such consultants and specialists as have returned the forms supplied to them have taken the opportunity of stating precisely the nature of their work, and general practitioners have indicated in many cases the professional studies in which they are particularly interested. At the end is an alphabetical index of towns with the names of practitioners there resident. The volume contains, besides, certain personal data which are otherwise not accessible. The list of questions to practitioners, on the answers to which the book is based, was submitted to the General Medical Council, which took no objection to them. The volume contains no name which does not appear in the Medical Register. It is well printed and produced in handy form for the reference shelf. The price is 30*s.*, from the Grafton Publishing Company, Ltd., 8, Stone Buildings, Lincoln's Inn, London, W.C. 2.

PEMPHIGUS NEONATORUM.

Two recent outbreaks of pemphigus neonatorum in maternity homes have induced the Ministry of Health to issue a Memorandum[1] on the subject. In the first outbreak 23 babies were more or less severely infected, the disease appearing first round the finger-nails and spreading thence to other parts of the body. Three mothers suffered from mammary disease, and there were two cases of puerperal fever, one of which proved fatal. In the second outbreak the number of cases was much smaller; all were slight in degree, and there was no infection among the mothers. There were no fatal cases in either outbreak and in neither could the source of the infection be ascertained. The Memorandum distinguishes between a mild type of pemphigus associated with little or no systemic disturbance and recovering within a few weeks, and a grave type which usually terminates in pulmonary œdema, the latter being the result of infection from an unhealed umbilical wound. No definite pronouncement is made as to the true causal organism, although most authorities consider pemphigus to be an infantile form or variant of contagious impetigo. In the mild type the portal of entry is presumed to be some slight lesion of the skin, the carrier being the mother, nurse, or midwife, either directly or through infected clothing, to which the infective agent seems to adhere with great tenacity. In the majority of outbreaks the attending midwife is the suspect; in one instance a small pustule was found on the midwife's finger, but examination has often failed to reveal any infective lesion. The first requirement in prevention is early diagnosis, and the Memorandum regrets the lateness in some cases of the report made to the local supervising authority. The midwife or nurse suspected of being the agent of spread should be suspended from practice until rendered free from infection and required to report after resuming practice. The disinfectant measures at present employed may reasonably cover a wide range since the mode or modes in which the disease may be spread are imperfectly known.

[1] Memo. 103 Med. H.M. Stationery Office. 1*d.*

INTRAPULMONARY INJECTIONS FOR INTRACTABLE HÆMOPTYSIS.

COPIOUS hæmoptysis is so serious a symptom and so alarming to the patient that any effective addition to the means of treating it is welcome. We publish a short clinical note from Dr. Andrew J. Morland, describing a case in which the direct injection through the chest wall of coagulen (Ciba) into a cavity was followed by the arrest of the bleeding with dramatic suddenness. There are on the market several compounds of this kind prepared from the serum of different animals. There is some evidence that they are useful in cases of hæmorrhage from the lungs, stomach, or bowels when given by subcutaneous or intravenous injection. Coagulen is said to be rich in thrombokinase, and its action is therefore readily comprehensible. The method would seem to be worthy of further trial in cases where copious and repeated hæmoptysis occurs. It is, of course, not always easy to determine in a given case with extensive disease the exact situation from which the bleeding arises, but in Dr. Morland's case it was known that there was a large cavity, and bubbling râles were plainly audible over it while the hæmorrhage was in progress. Experience with intratracheal injections has shown that the lung tissue will tolerate substances like menthol, guaiacol, and olive oil, reaching it through the air-passages. Modified serums of the type employed by Dr. Morland are usually bland substances, and it is therefore not surprising that they can be injected directly into a cavity within the lung. It is a recognised principle in surgery that where possible the bleeding point should be dealt with directly. Dr. Morland's attempt to apply the same principle to bleeding from the lungs is rational, and it is gratifying that in his case such good results were achieved. His experience would seem to warrant further trial of this method in suitable cases.

IMPERIAL ENTOMOLOGICAL CONFERENCE.

THE second Imperial Entomological Conference is being held in London from June 9th to 18th at the instance of the Imperial Bureau of Entomology, and summoned by the Secretary of State for the Colonies. This meeting is the outcome of the first conference held in 1920, when it was decided to hold such meetings every five years to further and coördinate the work of tropical and subtropical entomological research throughout the Empire. Particular interest should attach to this conference as it follows so closely on the international conference held in London last month [1] under the auspices of the League of Nations, for the purpose of setting up an international commission to study sleeping sickness in tropical Africa. The present chairman of the Imperial Bureau of Entomology is Lord Buxton, and the director is Mr. G. A. K. Marshall, D.Sc., F.R.S., assisted by Mr. S. A. Neave, D.Sc. The subjects which are being discussed at the Royal Society's rooms in Burlington House during the sitting of the conference deal with the widest aspects of entomology, and Prof. Warrington Yorke on Monday, June 15th, will consider the medical aspect in a paper on Coördination of Effort in Tsetse-fly Investigation.

MR. S. P. Vivian, whose name appeared in the Birthday Honours List with a C.B., was intimately associated with drawing up the medical benefits regulations under the National Health Insurance Acts, and, since his appointment as Registrar-General, has been freely accessible to suggestions for increasing the usefulness of his department to those engaged in health administration.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXVI.—THE TREATMENT OF HAMMER-TOE.

PART I.—GENERAL CONSIDERATIONS: CONSERVATIVE MEASURES.

Prophylaxis.

THE prophylactic treatment of hammer-toe deformity necessitates the use of shoes and stockings of sufficient length in the actively growing age, and correct posture in standing and walking. Shoes should be broad in the toe portion, straight along the inner borders, and not too pointed. The tendency to deformity should be detected early and rectified by the use of metatarsal bars or anterior arch supports, and by such active and passive movements as encourage the flexion power and range of the toes.

While the term *hammer-toe* is often loosely applied to any flexion deformity of the toes that may be found associated with various malformations of the foot, it should be more correctly reserved to describe a fixed flexion deformity. Of this there are two types, the *acquired* and the *congenital*, and in both the condition is commonly bilateral.

The *acquired* form is the more common; it involves the second toe, and is associated with hallux valgus, the combined deformity resulting from too short and too pointed footwear in the growing age, and from the improper method of walking with feet everted. The second phalanx is flexed on the first, and the latter is slightly over-extended at the metatarso-phalangeal joint. The terminal phalanx is in line with the second, or flexed or extended on it. The approximation of the tips of the great and middle toes buries the two terminal phalanges of the second toe, forcing them into a vertical position, while the proximal phalanx remains horizontal. The vertical portion of the toe is pinched at the top and bottom by the shoe; a painful corn forms on the head of the proximal phalanx and another on the tip of the terminal phalanx, just at the end of the nail, which becomes thickened and distorted. The tip of the toe is swollen, broadened, and flattened. On the dorsum of the metatarso-phalangeal joint the extensor tendons become contracted, maintaining the hyperextension deformity at this joint. A similar contracture occurs in the capsule and flexor tendons on the plantar aspect of the acutely flexed proximal interphalangeal joint, which after a time prevents straightening of the toe at this joint by passive movements. Occasionally the flexion deformity is in the terminal and not the proximal joint.

The *congenital* form differs from the acquired in that the middle toe is always involved, alone or together with the fourth and fifth. The proximal, and particularly the terminal, joints are both flexed to some degree; and the terminal phalanx is rotated and twisted, underlying its mesial neighbour. In infancy the toes can be straightened by passive movements, and are therefore amenable to conservative treatment. A slight adduction of the little toe alone, and with no disability, is so common that it cannot be considered abnormal.

In its less strict application "hammer-toe" may denote flexion deformity of the toes, associated with exaggeration of the long arch (*pes cavus*). All the five toes are involved, and usually bilaterally. These should be described as "clawed" rather than "hammer" toes. Hyperextension contracture of the metatarso-phalangeal joints is more marked than in real hammer-toe. Both the terminal joints are flexed, but the toes are drawn towards the dorsum of the foot, with no pressure effects on the tips, and the terminal flexion is more easily corrected by passive stretchings than in real hammer-toe.

---

[1] THE LANCET, May 30th, p. 1155.

In some cases of hallux valgus all the smaller toes are flexed in the two terminal joints and pushed backwards into adduction and dorsiflexion by pressure of pointed and short footwear, resembling "clawed" toes, but with the addition of the adduction. The great toe is valgus, and not "hammer" shape, thus distinguishing this boot-produced deformity from real pes cavus and claw toes, where the great toe is also hammer-shaped and less valgus. In rheumatoid arthritis the toes may be similarly deformed.

In any "hammer" and "claw" condition involving several toes, the anterior transverse arch is depressed and painful callosities form on the balls of the central toes. The corresponding metatarso-phalangeal joints may exhibit mechanical synovitis, due to weight stress being unrelieved by the deformed toes, which are unable to assume the normal flexion effort in the "push-off" in the last part of the step in walking. Toes that will not flex and grip the ground in the "push-off" are functionally useless.

The indications for treatment of real hammer-toe are: (1) The relief of pain from pressure on the dorsum of the prominent proximal interphalangeal joint or on the tip of the toe at the nail. (2) To fulfil the requirements necessary for admission into some of the public services. (3) For cosmetic reasons in children. There are two general procedures. (1) Conservative: By daily manipulations to correct the deformity passively, with retentive splints to hold the toes straight by day and night. (2) Operative: The gradual method is so tedious and lengthy that in anything but the slightest degree of deformity, even in the case of children, I strongly advocate early resort to operation.

Conservative Measures.

Conservative treatment is indicated in early cases of acquired deformity, and in children when the parents prefer it. For the single deformed toe of the acquired condition the best splint is a short covered metal one, of the width of the toe, and extending from the tip to the ball of the toe, where the splint is expanded into a small plate. This is fitted with a padded elastic loop passing over and exercising pressure upon the prominent proximal joint, and by tapes or elastic to fix the rear end to the mid-foot. It can be worn without discomfort within the shoe by day, and also at night. Various modifications of this splint are on the market and can be obtained from any foot appliance shop. Palliative appliances can also be obtained, consisting of an elastic sheath for the toe, with a sponge rubber pad attached, protecting the dorsal or terminal corns from pressure. These appliances take the place of the old strapping method, which was tedious. Splints are of service only in cases that can be corrected passively.

In the flexed and adducted third and lesser toes of the congenital deformity the use of a corrective splint is more difficult, on account of the twisting distortion and the smallness of the toes. The appliance used is a separate leather insole within the shoe, fitted with elastic loops for the toes. It is known as a "half-sole plate with loops," the half sole being fixed to the forefoot by a broad elastic band or tapes over the instep; it can also be used at night.

When appliances are used passive stretchings should be done morning and evening, to flex the toes at the metatarso-phalangeal joints, and extend them at the proximal and distal interphalangeal. While there is no doubt that in the slighter and earlier degree of deformity conservative treatment, if carried out with patience and assiduity, is successful, yet it is so slow and so expensive in time, splints, boots, exercises, &c., that operative treatment is mostly to be advised.

W. H. TRETHOWAN, F.R.C.S. Eng.,
Orthopædic Surgeon to Guy's Hospital.

(*To be concluded.*)

DARLINGTON MEMORIAL HOSPITAL.—Darlington's war memorial is to take the form of a new hospital. The cost will be £196,000, and there will be 228 beds and accommodation for 46 nurses. The Ministry of Health and Darlington Town Council will provide the maternity and skin diseases departments.

Special Articles.

ROYAL INSTITUTE OF PUBLIC HEALTH.

ANNUAL CONGRESS AT BRIGHTON.

MAY 27TH–JUNE 1ST, 1925.

THIS Congress was attended by some 300 delegates and members from all parts of the country, while New Zealand, France, Belgium, Switzerland, Portugal, and America sent representatives. Lord Leconfield acted as President of the Congress. In his address he referred to the interest Sir Henry Harben had taken in the Institute. As a not inconsiderable landowner whose tenants go in for milk a great deal he had been interested in seeing the report of a clean milk competition, but after reading it was profoundly grateful that his doctor had prohibited him from taking milk in any form. Papers were read on May 28th and 29th, both in the mornings and afternoons; receptions followed by dancing were given by the Mayors of Brighton and Hove at the Royal Pavilion, Brighton, and at the Hove Town Hall. On May 30th a visit was paid to Worthing, where the delegates were entertained to lunch by the Mayor of Worthing and to the home of Lord Leconfield at Petworth.

Much of the success of the Congress was due to the excellent arrangements made by the medical officers of health of Brighton, Hove, and Worthing.

SECTION OF STATE MEDICINE AND MUNICIPAL HYGIENE.

Sir Arthur Newsholme, in his presidential address, indicated some of the long overdue reforms in our administrative machinery called for by the advancing complexity of our problems. No abstract could do justice to the well-thought-out argument, the logic of which was invincible.

Dr. C. W. Hutt (M.O.H., Holborn) opened the discussion on

Immunisation against Diphtheria.

The aim of everyone who took up the work, he said, must be to get all the children living in the area immunised as soon after they reached the age of 6 months as possible. Preliminary Schick testing was found to be advisable at the Holborn Council's maternity and child welfare centre; retesting after the routine injections of the toxin-antitoxin, although unpopular with parents, was very necessary. Of 202 that had been retested 20 were found to be Schick positive after three inoculations; neither age nor sex nor interval after immunisation seemed to have any influence on the phenomena. His experience was that the reaction after the toxin-antitoxin was in most cases negligible.

Dr. W. T. Benson (Asst. M.O.H., Edinburgh) stated that three-quarters of the cases of diphtheria occurred after the child was of school age, but only 40 per cent. of the deaths. He described the routine carried out in connexion with the immunisation of the children in the Edinburgh schools. The consent of the parents to the treatment varied from 11–86 per cent., according to the social status of the parents and the attitude taken by the school staff. He found the presence of parents at the examination was a disadvantage; it upset the child and upset the routine. Although parents were invited to bring children of pre-school age to the school for immunisation, very few availed themselves of the invitation. The children were re-tested from six to nine months after immunisation.

Dr. S. Monckton Copeman (late Ministry of Health) dealt with the difficulties of diphtheria immunisation; although the procedure was not difficult to learn some initial practice was necessary; the statistics were unreliable if the difficulties were not appreciated. He referred to the need of the injection being intradermal, and was in favour of the first injection even in school-children being 1/10th c.cm. of toxin-antitoxin. This injection could be given when reading the preliminary Schick test; if advisable the child could be given 1 c.cm. of toxin-antitoxin at the time of reading; in this way very little time would be lost and the chances of reaction minimised. He found that in the Farnham Poor-law schools, where the children came from rural areas, there was very little immunity present among the children, and they were correspondingly hard to immunise. He thought that no nurse or ward-maid should be asked to work in diphtheria wards unless she had been found to be Schick negative or had been immunised.

Dr. Duncan Forbes (M.O.H., Brighton) thought that the work should start first with the children in residential institutions in a town. All nurses in fever hospitals, all children suffering from scarlet fever, and all tuberculous children admitted to isolation hospitals should be immunised.

Dr. S. G. Moore (M.O.H., Huddersfield) gave an example where excessive instances of diphtheria had occurred among non-immunised children as opposed to the immunised children in the same school.

The same subject was dealt with in another Section by Dr. H. Stott (M.O.H., East Sussex Combined Districts), who had gone to the trouble of collecting several instances where immunisation had been carried out on nurses in fever hospitals.

Tuberculosis and Employment.

The discussion was opened by Dr. P. C. Varrier-Jones, who had been driven to the conclusion that in tuberculosis the unit to be dealt with is the family. Papworth was a sanatorium with 120 beds; in addition some 70–80 houses had been built for families of tuberculous men where they could live with their families and earn a wage to supplement their war pensions. The disability of the men varied from 20 to 100 per cent. In the outside world consumptives were refused work partly owing to the fear of infection, but more because employers feared that the consumptive would not be able to earn his wage. At Papworth they were producing three times the quantity they were three years ago. The unskilled man could be dealt with; he was quite content to work as a machine-minder doing repetition work. Tuberculous women could be fitted in with men in the colony. The foreman and managers should be consumptives; they took a more sympathetic view of the ailments and state of health of the workers; again, consumptives are very suspicious of healthy overseers.

Dr. Neville Cox (T.O., Brighton) stated that schemes to provide work for the tuberculous male population as a whole had been found to be too costly. He referred to the report of the Barlow Committee. The success of Papworth was due to the benevolent autocracy of Dr. Varrier-Jones. One advantage of Papworth was that the only qualification required was that the patient had tuberculosis; his sputum need not be free from tubercle bacilli. But for various reasons only a small proportion of the patients would go to Papworth; for the bulk work must be found in the ordinary industrial world. Apparently there was very little work a consumptive could not do, but there was real danger, however, in any tuberculous person looking after babies or children and in their close association with young adults, and a risk in their handling food. From statistics published in the Brighton annual report for 1923 it would appear that work in connexion with transport, such as tram and bus conductors, and taxi-cab drivers and railway work had the largest proportion of patients at work. Of 39 clerical workers 29 were at work. The critical time for a patient was the first two years after leaving sanatorium. Many of these were then fit for few hours work; these men ought to be employed in municipal workshops. An experiment is being made in Brighton where four men are engaged in woodwork, machinery being used; any work done is used for corporation purposes.

Mr. G. W. Allen (manager of the Factory in the Field, Leeds, situated in its healthiest suburb) gave an account of the work being carried on. The men lived in the city; the working day was spent in the healthy environment provided by the factory. Most, if not all, of the men he dealt with were ex-Service men with pensions varying from 8*s.* to 40*s.* per week. Over three years ago a society of these tuberculous men was formed; it was registered in order to limit the liability of the men. They started with £3000, apparently clubbed together from the tool grants provided by the Ministry of Pensions, and £3000 loaned by Lord Haig from the British Legion Funds. The key to the position was the use of machinery to avoid strain. They started with two army huts provided with the best electrical machinery for the particular work first taken up, the splitting and binding of firewood. Boot-making and repairing had not proved satisfactory because they had not been able to purchase the best machinery for the purpose. Brush-making, a skilled occupation, was their best trade. A few of the patients had been trained as commercial travellers and were paid £3–£4 per week and expenses. General utility work had been found useful—four men under a foreman who had been a joiner were engaged in small repairs to cottage property; they did anything from mending a water spouting to laying concrete. Removal of colliery refuse heaps from the areas within the city boundary had been remunerative.

Dr. H. de C. Woodcock (late T.O., Leeds) stated that 20 per cent. of the men who were working in the Leeds factory have tubercle bacilli in their sputum, a much lesser proportion than at Papworth. Although there had been hæmorrhage and actual deaths among these working patients he held that no more deaths occurred than if they had not been at work. The psychical value of work for the tuberculous was very considerable; any hope of recovery was taken away if the men were told they were no longer fit for work.

Several speakers referred to the attitude taken by Henry J. Ford, who considered that manufacturers should not only employ selected samples but all the members of the ordinary population of the district. He had found employment for tuberculous persons and even for the blind in his works.

A kinema demonstration on the Colony Treatment of Tuberculosis was given by Dr. Varrier-Jones.

Valuable papers on ionisation in ear discharge were delivered by Dr. A. R. Friel and Dr. R. Cramb (Brighton); evidently all engaged in treating school-children should follow these pioneers. A paper on the dental treatment of school-children was read by Dr. L. A. Parry (S.M.O., Hove) and Mr. Mackay, L.D.S. (Brighton).

Obstetrics and Public Health.

The discussion was opened by Prof. Louise McIlroy, who suggested that a panel of obstetricians should be formed among general practitioners who were interested in obstetrics; they should also be in charge of the antenatal clinics; in rural areas whole-time medical officers should be appointed to do the midwifery. Obstetrics should come under the public health service. She thought that the inspection of midwives by doctors was objected to by the persons inspected; this should be done by midwives of long experience such as the matrons of maternity institutions. Ordinary general practitioners were not suitable persons to serve on the staff of antenatal clinics; much experience was necessary, also study in the continental capitals such as Paris, Berlin, and Vienna; not enough material was available in London. It was not enough to have been a house surgeon for a year at an obstetrical hospital. She objected to notification of puerperal fever, and pointed out the lack of institutional accommodation for tuberculous pregnant women.

Dr. Eardley Holland dealt with stillbirths. He gave an account of the procedure of the subcommittee at Geneva which was appointed to arrive at a definition of stillbirth; difficulty had occurred as to the fœtus in transient postnatal stage of its life. Usually the fœtus when born breathes at once and becomes a child; occasionally it has a postnatal existence and this causes confusion. The subcommittee had decided that breathing or a cry should be the sign of life; many births are attended by women of very little medical knowledge and these signs were easily recognisable. The placenta should always be examined as well as the fœtus if a post-mortem examination was made. The cause of death might be found to be retroplacental hæmorrhage, necrosis, or infarction. The part played by syphilis in causing stillbirth had been very much exaggerated. A syphilitic placenta could not be recognised as such by the naked eye; only one-fourth of all macerated fœtus and about one-tenth of all cases of viable fœtal death were due to syphilis. Every macerated fœtus should be examined post mortem for the existence of syphilis; enlargement of the long bones (osteochondritis) was the cardinal sign. The enlarged liver or spleen did not necessarily mean syphilis. Antenatal supervision, the strategy, was of no use without skilled attention during labour, the tactics. He thought that considerable medical skill was required to diagnose the minor degrees of pelvic contraction and to assess correctly the reproductive history of a woman. Early diagnosis of the toxæmias of pregnancy was not easy. The advocacy of an obstetric service was useless as it could not be manned. The teaching was very poor at present; we should strive for the better education of medical students and all doctors in post-graduate courses.

Dr. Moore pointed out that from 1901–24 in his borough area the death-rate among all mothers was 5·69 per 1000 births. Among those who voluntarily notified their pregnancy the death-rate was only 2·43.

Dr. G. Q. Lennane (M.O.H., Battersea) pointed out that owing to the rigid rules laid down by the Ministry of Health only 50 per cent. of the beds were occupied at the Battersea Municipal Maternity Hospital.

Dr. R. D. Smedley (M.O.H., West Sussex C.C.) considered any special accommodation available in workhouses used as a temporary measure. The local authority should pay for such accommodation and the mothers would then be admitted as private patients. He had made such arrangements for difficult cases and found it of great assistance. He thought that tuberculous mothers might be left out of the question; they should not have children; they were told so at the sanatorium, and things should not be made too easy for them. He had found that the inspection of midwives by a doctor had done a great deal to improve the practice of midwives, especially in the introduction of abdominal palpation.

Dr. H. Scurfield (late M.O.H., Sheffield) said that when antenatal clinics were started it was thought that the work would be confined to giving advice in cases of healthy women, but experience has shown that work in connexion with women whose health and physical condition was abnormal was needed. For antenatal work he thought that an experienced obstetrician was required.

Dr. D. Forbes saw no objection to the notification of puerperal fever. All that happened was that the M.O.H. obtained from the doctor a few particulars, and he was able to help the doctor by obtaining removal of the patient to hospital. He thought that the charge made by the doctor called in to render medical help was too high.

Prof. McIlroy, replying, thought that one advantage in the attendance early in pregnancy at the antenatal clinic was that arrangements could be made for the mother's confinement in good time. She thought that one of the objections of women to going into a Poor-law infirmary was that it could always be seen from the birth certificate of the child that it was born under the auspices of the Poor-law.

Control of Venereal Diseases by the Public Health Service.

The discussion was opened by Col. L. W. Harrison. He thought that the crying need at present was for better treatment of gonorrhœa. It was very wrong for a mother to bear one syphilitic child after another; propaganda in this respect should not only be left to societies—a word in season by the general practitioner would be of very great value.

Dr. F. H. Lawson (V.D. officer, Brighton) had found that it takes longer to see a patient in an ordinary out-patient department than in a special place set apart for the purpose.

Dr. Forbes stated that his experience was only a small amount of arsenobenzol was sent out locally from the Public Health Department and much of that was used by the V.D. officer in his private practice and by members of the honorary staff of the hospitals. In cases of stillbirth the midwife was paid 5*s.* for bringing the body to the Health Department which undertook its subsequent disposal. The liver was sent to the pathologist—in about 15 to 16 per cent. evidence of syphilis was found. The parents were informed, but very great difficulty was experienced in getting them to attend the clinic for examination and treatment if necessary, although the way was made easy for them by offering special appointments. In Brighton the V.D. officer is in close touch with the infant welfare centre, but unfortunately women will not go to the V.D. clinic to the extent that they should.

Dr. R. A. Askins (Bristol) considered that the divorce of the Public Health Department from the work of V.D. schemes constituted a real danger. Most of the V.D. work was carried out in practically watertight departments of hospitals. The M.O.H. was only an onlooker; this was all the more unfortunate, as he is usually an excellent propagandist, closely in touch with the general practitioners and the educationists of the town.

Dr. F. Bowerbank (New Zealand) mentioned that in New Zealand the number of women receiving treatment was very small; it was evident that many women were not receiving treatment. He thought that V.D. was better treated by a specialist than by a general practitioner.

Mrs. C. Neville Rolfe (British Social Hygiene Council) hoped that their Council would now be able to influence the adolescents of both sexes. In Canada and the United States to every V.D. centre was attached an almoner who dealt with the families of the patients and not with the patient alone. In this country we were doing a certain amount for girls but very little for boys. She referred to the Big Brother movement of the United States, where boys needing social adjustment were passed on by the almoner to a committee largely composed of business men interested in the Rotary movement. She hoped that as a result of the new Council's efforts they would be able to raise the standard of cleanliness and self-respect, and that in consequence the supply of professional prostitutes would be reduced.

Colonel Harrison, in replying, stated that great emphasis was laid on the importance of including general practitioners when the schemes were initiated. There is still free access to clinics, but practitioners do not attend to any extent. He agreed that very little use was made of the free supply of arsenobenzol, and felt also that the arsenobenzol that was given out was not used properly, each case evidently receiving two or three doses only. He agreed with Dr. Bowerbank that V.D. is better treated by a specialist; there was enough in syphilis alone to make a specialty in itself; a study of the treatment of gonorrhœa was brain-racking. General practitioners say they see so very little of venereal disease; they are apparently doing very little treatment, but they should certainly be trained to such a degree that they can diagnose a case of venereal disease when they see it. The Public Health Department and venereal disease scheme started divorced. The Ministry of Health are now doing their best to bring these two bodies together. Letters are frequently sent out from the Ministry suggesting that the V.D. officer should be on the staff of the M.O. or appointed as his adviser in V.D.

Surg.-Cmdr. R. T. G. Parnell's paper, read in the Military Section, dealt with carefully observed series of cases of syphilis in which bismuth was used; it should be read by all those who are engaged in dealing with syphilis. Bismuth, he considered, has largely replaced mercury; it is more effective, far less toxic, and its effects on the patient are far less unpleasant; it was specially useful for chronic glossitis and chronic leucoplakia of the mouth. Unfortunately the mercury pill had no analogous bismuth preparation.

A film on the Treatment of Gonorrhœa in the Male was shown by Colonel Harrison.

Section of Naval, Military and Air Force Hygiene.

In this Section, presided over by Sir William Leishman, a discussion on the

Teaching of Hygiene in the Army

was opened by Lieut.-Colonel J. A. Anderson, professor of hygiene at the Royal Army Medical College. Certain officers are selected for training as specialists in hygiene at the end of the general senior course of two and a half months taken after eight to ten years' service. The course lasts six months; the officers are required to obtain a Diploma of Public Health and also a knowledge of the application of the principles of hygiene to an army community both in the barracks and in the field. Included in the course is the study of the medical aspects of recruiting to which a whole month is devoted. To assist the student of army hygiene and sanitation two official text-books are available, an elementary one, "The Manual of Sanitation in its Application to Military Life," dated 1920, the other issued to all R.A.M.C. officers, the "Manual of Military Hygiene," 1921. Colonel Anderson thought that printed or pictorial propaganda of a popular type should be more used in the army.

General Sacquepée (France) gave an account of the teaching of hygiene in the French Army. He thought that the men being taught the value of cleanliness and simple hygienic measures would have a marked effect on the health of the civil population when these short-service soldiers returned to civil life. He mentioned that the addresses to the private soldier were supplemented by "tracts" and posters often conveying a pictorial lesson, but he placed even more reliance on the film.

Surg.-Cmdr. G. R. McCowen read a paper on the M.O.H. and Chemical Warfare, which has been very fully reported in the lay press. Major-General W. H. S. Nickerson, V.C., remarked that unless medical officers of health were fully informed as to the probable number of casualties, and the kind of casualties, they obviously would not be in a position to deal with the problem.

The paper Routine Pathological Examination as Applied to Physiologically Inefficient Aviators was read by Wing Commander H. E. Whittingham, Director of Pathology for the Royal Air Force. He said that flying might strain the physiological functions of the body in various ways; the general alertness required used up much nervous energy; high altitudes accelerated the rate of breathing and the circulation producing changes in the whole metabolism. Pathology was physiology gone wrong. The flying personnel were systematically kept under physiological observation. In this country the Central Medical Board at Hampstead dealt with any conditions which could not be remedied at a station and also with all aviation candidates. If the Board decided that any case was physiologically inefficient or doubtful, specialists performed further tests to detect, if possible, the cause and to aid in the assessment of the probable duration of the disability.

Section of Industrial Hygiene.

In this Section excellent papers on Smoke Prevention were read by Dr. C. S. Thomson (M.O.H. Deptford), and Mrs. M. H. Cloudesley Brereton and Mr. T. M. Horobin; Dr. C. O. Stallybrass (Asst. M.O.H. Liverpool) spoke on Occupational Cancer.

Miss Gertrude Smith (Bootle), speaking on the routine of welfare work in the factory, contrasted the excellent arrangements made for the work girls with those made for health visitors.

Section of Tropical Diseases.

This Section was presided over by Dr. Andrew Balfour. His presidential address was on the term "tropical," and he also gave to the Section a demonstration of the Rockefeller malaria film.

Sir Leonard Rogers, in the course of a paper on Disease Incidence and Climate in India, spoke of India as an ideal field for studying the influence of climate on disease. He referred to the close relationship between high rainfall and high leprosy incidence, and humid monsoon winds and high phthisis rates; and he indicated chills as the most important cause of malaria. Marked falls in the number of small-pox cases were seen when high degrees of humidity occurred during the monsoon months. In years of failure of the rains the decline was much less during the monsoon months, and consequently the rise which the succeeding cold, dry weather invariably brought, started from a higher level and an epidemic resulted. In most parts of India the principal small-pox epidemics could thus be foreseen, in future, in time to allow of special efforts to push vaccination in the affected areas.

General Gouzien, of the French Colonial medical administration, gave an interesting account of the measures adopted to combat sleeping sickness in the French colonies. The work was very thoroughly organised throughout an enormous area; villages were even moved to bring them on the lines of communication. The success attending the French system of training natives to take part in the laboratory work aroused the admiration of Sir William Leishman.

Section of Pathology, Biochemistry, and Bacteriology.

The outstanding features of this Section were the presidential addresses and two papers dealing with vitamins. Prof. E. C. C. Baly (Liverpool) in his address dealt with the anabolism of the simpler compounds and the construction of proteins by plants. The light of the sun does more than photosynthesis; it maintains the compounds formed in a state of high energy so that plants can carry out their vital functions. The healthier a plant the higher is its food value; this depends upon the plant's high vital energy. He held that vitamins were not specific chemical compounds, but were substances normally present in food in a state of high chemical energy.

Women and the Public Health.

The opening address was delivered by Miss Margaret Hardy, J.P.; the afternoon session had as Chairman Mrs. Cooper Rawson.

In the discussion on Heliotherapy and Actinotherapy Sir Henry Gauvain stated that for heliotherapy we wanted intermittent exposure to sunlight; he questioned if sunlight by the sea were not as good as the much-vaunted Alpine sun. Dr. Leonard Hill, speaking of ultra-violet rays produced by lamps, said that so far as he could find out real and artificial sunlight produced the same effect.

On the second day the subject of birth control was discussed by Dr. Mary Scharlieb, Dr. Norman Haire, and Dr. M. M. Chadburn. The discussion has been fully reported in the lay press, as was also the sermon preached on the same subject by the Bishop of Birmingham, F.R.S.

A model popular lecture on the Plague in Britain in Past Centuries was delivered by Lieut.-Col. W. P. MacArthur to a large and representative audience on the Saturday evening, May 30th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Transplantation.

THE principal subject discussed by the recent German Surgical Congress concerned transplantation and its results. The discussion was introduced by a paper read by Prof. Lexer, of Freiburg. He stated that such homoplastic transplantation of entire organs—pancreas, thyroid gland, hypophysis, kidney, and suprarenal capsule—as had been tried had not had any lasting result. Bier and Carell had successfully transplanted entire extremities in dogs, but Prof. Lexer had not been so successful himself; his best case was that of a transplanted femur, but the leg became necrotic after 24 days, although the circulation had apparently been re-established. Concerning individual organs, he said that homoplastic material had often been a failure when autoplastic material was not attainable. Transplantation of epidermis and of skin should be performed more frequently as there excellent results were obtained, the former being successful on an average in 90 per cent. of cases, the latter in 75 per cent. Transplantation of bones with periosteum and bone-marrow also gave good results. The restoration of the function required rather a long time, at least one year, and three years when the naked bone without periosteum had been transplanted. It was essential not to strain the extremity too early. In bones transplantation of homoplastic material was sometimes successful, whilst heteroplastic material produced marked irritation with suppuration leading to a necrosis of the transplanted bone. Transplantation of joints might be successful under the same conditions, but homoplastic material led to healing only without giving motility to the joint. Cartilages were well suited for transplantation as they had a marked tendency to adhere to the substratum. Homoplastic material might be dispensed with, as ample material was at the disposition of the surgeon in the cartilages of the ribs and of the ear. Previous to a transplantation of a tendon, the joints concerned must first be made movable, if necessary by a plastic operation. To replace a tendon a strip of periosteum or of the fascia lata might also be taken. To avoid adhesion Prof. Lexer recommended the implantation of fat. He had performed 330 operations for mobilisation of joints in this way, and on one occasion used a lipoma from an old woman for this purpose. A drawback was, however, that hæmorrhage might occur in fatty substance. Fat was also useful in filling cavities of bones and defects of the dura mater. In six of 17 cases of defects of the dura mater filled with fat the epileptic fits had ceased. In transplantation of vessels the homoplastic method was uncertain, but autoplastic material taken from the vena saphena gave good results. It was not yet possible, he said, to give a definite judgment on transplantation of nerves, while free transplantation of muscles had always been a failure.

University of Münster.

The number of universities in Germany is still increasing. Shortly before the war new universities were opened at Hamburg and Frankfort. As a result of the war Germany has lost Strasbourg, one of its most important universities where the medical faculty has been especially flourishing, but Cologne has been opened since with its great and well-equipped hospitals. A recent addition to the centres of medical learning was the completion of the University of Münster, the capital of Westphalia, one of the oldest cities of Germany. The University of Münster had consisted for a century of a philosophical and theological faculty only, but shortly before the war a medical faculty was added which was at first rather incomplete, giving opportunity for the study of the preliminary branches of anatomy, physiology, and natural sciences only, and not for clinical medicine. Now the faculty has become complete, a series of new clinics has been built and these were lately inaugurated in the presence of many representatives of the Government, other medical faculties, and of the medical profession. The new premises, though constructed in a plain architectural style to save superfluous expenses, are, nevertheless, furnished with modern apparatus and laboratories. Forty-five students have already matriculated for clinical study. A number of "honorary citizenships" of the university were conferred at the opening ceremony on prominent medical men.

Alcoholism in Germany.

One of the few good effects of the war was the decrease of alcoholism in Germany. Spirits could not be purchased at all or only at a prohibitive price. The result was that the number of mental diseases due to alcoholism decreased greatly. The lunatic asylums of the city of Berlin, for example, became sparsely inhabited and a new asylum, which was to be opened at the end of 1914, became superfluous, so that its premises could be dedicated to other purposes. Similar examples occurred throughout Germany. According to a statistical record of the clinic for mental diseases of Breslau University, the proportion of mental diseases due to the abuse of spirits was estimated before the war at not less than 40 per cent., which decreased in war-time to 7 per cent. After the war, in 1919, 100 new spirit licences were granted, with the result that the proportion increased in that year to 15 per cent., in 1920 to 17·3 per cent., and in 1921 to 32 per cent. In 1922 there was again a decrease to 31 per cent., and in 1923 a still further fall to 22 per cent. The reason of that decrease was that the spirits became in the latter year much more expensive owing to heavy duties and that by a by-law in Breslau the sale of spirits was prohibited from 9 P.M. to 8 A.M. In other cities there is a similar state of things, as shown by reports from the clinics for mental diseases of the Universities of Munich, Cologne, and Frankfort. Undoubtedly the nuisance of alcoholism requires energetic measures, but radical prohibition as in the United States would probably never meet with the approval of legislation in this country. The adherents of "No Prohibition" are very busy and even sometimes do not refrain from violence, as shown by an incident which happened lately in Berlin. The Church Anti-Alcohol Society had convoked a meeting in Trinity Church where an address was read by a clergyman. He was frequently interrupted by a noisy mob who even tried to assault him, so that the police had to enter the church to protect him and the congregation. It must, however, be stated that the indiscriminate drinking of beer has much decreased in academical circles. The German student who formerly used to spend a good deal of his time in "Kneipen" has largely abandoned that custom and sports of every kind now widely fill the hours formerly spent in smoky and badly ventilated restaurants.

Gonorrhœal Arthritis in Infants.

Dr. Knauer, of Breslau, reports in the *Zeitschrift für Kinderheilkunde* a case of gonorrhœal arthritis in a female infant, aged 7 days, whose parents were both infected with gonorrhœa. On the seventh day after birth reddening and swelling developed on the left prepatellar bursa and three days later the great toe also became affected. On aspirating the bursa purulent fluid was evacuated containing gonococci. The swelling of the bursa and of the toe gradually diminished and the infant was completely restored to health. No fever had occurred. The portal of infection could not be determined as neither the conjunctiva nor the vulva of the infant was affected; possibly the gonococci entered through the umbilical wound or through the skin, where some small pustules were present. Two other cases were reported by Dr. Fischer. The shoulder-joint was affected in both cases. On aspiration gonococci were found in the one case, whilst in the other the culture was sterile.

Gas-masks against the "Haff Disease."

The so-called Haff disease, described some time ago in these columns,[1] which by thorough investigation was traced to poisoning by arseniuretted hydrogen, has not yet been entirely eradicated, although the waste waters from the factories, whence the disease originated, were partly diverted from the Haff. In the month of May 20 new cases occurred not only among fishermen but also among persons working near the Haff. The Government has therefore provided the fishermen with gas-masks similar to those used during the war, but some of the men have declined to wear them, on the grounds that they interfere with their work. It is to be hoped that, by and by, the more conservative fishermen will get accustomed to the mask, which does give effective protection.

First-Aid Lessons by Films.

The Red Cross has arranged for an instructive film to be shown to the public in the leading kinemas. The film was lately demonstrated privately to a selected audience, including many medical men. In the first part the aid to be given in cases of wounds was shown, where special stress was laid on the prevention of infection in wounds and where the application of the "Verbandpäckchen" (first-aid packet) was demonstrated. The second part dealt with first-aid in fractures and dislocations, showing the use of improvised splints. The evil effects which might result from attempts by the uninitiated to set a fracture or reduce a dislocation were demonstrated and the necessity of calling a surgeon was emphasised. The third part dealt with first-aid to be given to the apparently drowned, in cases of frost-bite and sunstroke, and in other accidents of that kind. The pictures were well produced and easily intelligible to a lay public.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1924 of a group of districts of varying local government status :—

Name of district.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Southport C.B.	73,650	12·9	13·7	1·07	1·4	2·6	31	63	1·1
Bilston U.D. ..	30,310	26·5	12·6	0·72	0·9	4·4	39	97	0·0
Radcliffe U.D.	25,290	15·4	14·1	0·80	1·1	2·8	51	102	5·1
Barnstaple R.D.	18,520	14·2	12·3	0·75	1·6	1·8	—*	42	3·8
Adwick-le-Street U.D.	14,750	33·4	8·6	0·74	0·5	1·6	—*	71	6·1
Bentley-with Arksey U.D.	14,430	24·6	8·6	0·41	0·3	2·3	—*	93	8·4

C.B. = County borough. U.D. = Urban district.
R.D. = Rural district. —* = Information not given in the report.

Southport.

Dr. G. C. Barnes reports that the hours of sunshine in Southport during 1924 were 1410·4, and that nearly the whole of the large shortage of sunshine occurred during the summer half-year of April to September. The population of Southport is almost entirely residential, with the necessary auxiliary occupations. There is one important motor works. The notification of tuberculosis is still unsatisfactory, and the health committee have resolved that cases of failure to notify shall be taken before the magistrates, in accordance with the regulations of 1925. The arrangements for the treatment of surgical tuberculosis leave much to be desired, but Dr. Barnes points out the wide distinction between pulmonary and surgical tuberculosis from the point of view of the sanitary authority, in that the latter, while causing grave personal disability and loss, is generally regarded as non-infective. He suggests, therefore, that surgical tuberculosis should in principle be dealt with by voluntary institutions. One out of ten samples of milk produced inside the borough was found to be tuberculous, and seven out of 84 outside samples. The four samples of "certified milk" submitted to bacteriological examination proved to be well above the standard. The council of Southport have protested four times against the continued suspension of the Tuberculosis Order of 1914. 309 new houses have been completed by private enterprise during the year. The high cost of labour and materials, however, interferes both with the construction of new and the repair of old houses. New houses are still needed for manual workers and other persons with small means. Southport is in an exceptional position, seeing that the deaths exceeded the births by about 30. Presumably the new houses partly provide for new residents.

Bilston.

Dr. T. Ridley Bailey reports that the year under review has been one of marked progress. A scheme for the substitution of 910 water-closets for privies has been successfully carried out. New storm-water and detritus tanks have been provided at the sewage disposal works. The sewering of the Moxley area has been completed, and every house in that district provided with water-carriage. "The chief blot is, of course, the state of overcrowding." Nevertheless, Dr. Bailey congratulates the council on their efforts. Since 1919 the council have erected 649 houses, and at the present time they have under consideration a scheme for the erection of 492 houses, and another scheme under private enterprise for 70 more. At the 1911 Census the number of persons per house was 4·96. At the 1921 Census the number was 4·25, and it is estimated that to-day the number of persons per house is 5. Recent efforts have, therefore, not provided for the annual increase in the population. "Some of the conditions found by the inspector during his visit were appalling." No proceedings can be taken for overcrowding. The only solution of the problem is the erection of more dwellings, and, says Dr. Bailey, "any man or any body of men, under whatever pretext, preventing or delaying this work is an enemy to the State." The health visitor's report shows that of 728 babies 662 were breast-fed, 28 partly breast-fed, 3 received breast milk and solid food, and 35 were artificially fed at the time of the first visit; also that 235 of the babies had a "dummy" and only 64 were provided with a separate cot. The report under review is the fortieth which Dr. Bailey has made during his term of service.

Radcliffe.

Dr. John M. Gibson comments on the increase in infant mortality from 74 in 1923 to 102 in 1924, and states that most of the Lancashire districts also show a marked increase. Infant mortality has always been very high in Radcliffe, as shown in a table giving the mortality for every fifth year. The figures are 222 for 1895, 198 for 1900, 155 for 1905, 148 for 1910, 145 for 1915, 115 for 1920, and 102 for 1924. As in most districts, there has been no decline among the deaths during the first week and month of life. The opening of a maternity home in the district is urgently needed, especially in these times of overcrowding. Dr. Gibson points out that the Bealey Memorial Convalescent Hospital (eight beds) is in danger of being closed owing to lack of funds, and he suggests that this building is admirably adapted for use as a maternity home.

---

[1] THE LANCET, 1925, i., 566.

An outbreak of encephalitis lethargica has caused considerable anxiety. One case of this disease was notified in 1920, and none in the three subsequent years. During 1924 11 cases were notified, none of which ended fatally. One of the survivors has left the district, and her subsequent history is unknown. Of the remainder, only four have made complete recoveries. Three manage to perform their ordinary duties, and three are physically unfit for any work 12 months after the attack. The 11 cases seemed to have no relationship to one another, and in no instance was there a second case in the household. During the last quarter of the year there was an outbreak of measles, numbering about 700 cases, with seven deaths, all under the age of 5. Dr. Gibson suggests that it would be advantageous if measles in children under 5 years of age were made notifiable. For many years the opening of a maternity and child welfare centre has been under discussion. When the report was issued this event was expected to take place on April 2nd, 1925. The building is an excellent one for the purpose, having large bright rooms and being surrounded by a public park. Since October, 1921, a scheme has been in force for the conversion of privies into water-closets. The number of privies, which was 1863 in 1921, has been reduced to 880 in 1924.

During the year particular attention has been given to the purity of the milk sold in the district. In commenting on " purity " tests Dr. Gibson points out the unsatisfactory nature of the " deposit " test, as every cow-keeper was able to forestall this test by providing a fine sieve to strain out the dirt. The bacterial count gives much more satisfactory results. No milk purveyors in the district have applied for licences to sell " graded " milk, but a fairly successful effort has been made to get the " Grade A " standard of purity made general. Of 29 samples of milk examined 27 reached the Grade A standard for bacterial count, and 13 for the absence of *Bacillus coli*. Only four samples were examined for the presence of tubercle, and one of these was found to be infected. In addition to the local supply of bread, a considerable amount is received from neighbouring towns, and a large proportion is wrapped in waxed paper. There are nine slaughter-houses in the district, eight registered and one licensed, and the new meat regulations, with the provision for three hours' notice of the intention to slaughter, will facilitate inspection " enormously." Dr. Gibson refers to the important conference on smoke abatement for the area round Manchester held during the year, and attended by representatives from 78 authorities.

A valuable series of hints to boiler attendants compiled by Inspector Clinch, of Halifax, have been circulated to all the factory owners in the district. As regards housing, Dr. Gibson reports that 96 houses have been added during the year, that 38 more are in course of erection, and that plans have been prepared for a further 50, and that when these have been completed the urgent demand for houses will have been met.

Barnstaple.

Dr. J. R. Harper reports one case of encephalitis lethargica at Combe Martin which recovered, and a fatal case in the North Devon Infirmary admitted from Wrafton, outside the district. During the early part of the year there was a widespread outbreak of influenza, more severe in type than that of the three previous years. Nine deaths resulted. The abnormal rains of 1924 severely taxed the drains and sewers of the district, and many complaints of flooding were received from Braunton. Most of the water-supplies in the villages are excellent. Combe Martin has now in hand a scheme for an adequate public supply.

Adwick-le-Street.

Dr. A. B. Dunne points out a discrepancy with regard to the deaths from childbirth coming to his knowledge and the figures supplied by the Registrar-General, the numbers being five and three respectively, equivalent on these small numbers to the high death-rate of 10 or 6 per 1000 births. Twenty-one cases of small-pox were notified with no deaths.

Bentley-with-Arksey.

Dr. Dunne also reports for this district, in which there were no cases of small-pox notified. In both districts the use of vans as permanent dwellings is becoming very common, and hitherto, unless a nuisance could be proved, the sanitary authority has had no power if the vans were on wheels. This has now been altered by the judgment delivered by the Lord Chief Justice in the case of Keeling *v.* Wirral R.D.C., by which such vans are temporary buildings and subject to the by-laws of the sanitary authority in districts where Section 27 of the Public Health Acts (Amendment) Act, 1907, is in force. Dr. Dunne returns to the question of the smoke nuisance, and trusts that the public will take sufficient interest in the matter to ensure the passing of the proposed Smoke Abatement Act.

SCHOOL MEDICAL SERVICE.

STATISTICS from three school medical reports for 1924 are given in the following table :—

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	Special examinations or inspections.	Percentage of children found on routine examination requiring treatment.‡
Torquay	3000*	—†	1113	4234	15·5
Eastbourne . .	4883	4478	1573	8467	18·6
Leamington Spa	3347	3018	1046	1348	8·8

* Approximately. † Not given.
‡ Excluding uncleanliness and dental defects.

Torquay.

The school medical officer, Dr. T. Dunlop, on introducing the assistant S.M.O.'s (Dr. J. V. A. Simpson) report, remarks on the importance of his special investigations. Dr. Simpson carries out the treatment at the welfare centre and so is able to follow up the health of many children from birth to school-leaving age, and instances several cases of incipient defects—e.g., tonsils, squint—satisfactorily treated in pre-school children, ensuring that such children may start school-life without handicap. Dr. D. Wilson, the ophthalmic surgeon, congratulates the district on the close coöperation between the welfare centre, the school medical service, and the parents as is shown by the increasing numbers of young infants brought to him for treatment.

In his account of the open-air school, Dr. Simpson's enthusiasm is justified by the results obtained. The many advantages are clearly outlined in the advance in health and morale of the debilitated child and in the financial gain to the community from turning out healthy youngsters in place of confirmed invalids. Torquay is fortunate in the possession of open-air accommodation for 3 per cent. of its whole school population. Dr. Simpson, in his special investigation at the open-air school, reasons out the difficulties of precise definition of " nutrition " for obtaining standards for comparison, and wide references are made to various authorities. He finally adopts the Baldwin-Wood method and counts as malnourished all below 7 per cent. of the standard weight for age, sex, and height ; on applying this to the records of 148 children extending over a period of four and a half years, he finds that one out of every two children were below the limit on admission as against one out of every five on leaving. He further shows that the children remaining malnourished increase, on the average, more in height than do the others.

From his results it might be inferred that the consistently malnourished child has a constitutional bias which remains true to type in spite of a favourable environment and is in a class quite distinct from the malnourishment resulting from illness, bad feeding and housing. He disarms criticism by himself pointing out the paucity of data, and using an American standard for English children. The ventilation of the schools has also engaged Dr. Simpson's attention. He has employed Leonard Hill's katathermometer freely and tabulated the results of his experiments. The charts given show strikingly high readings of both dry and wet katas in the open-air sheds which contrast strongly with the low readings in some of the schools. The findings generally were in conformity with the sensory impressions obtained. A chart showing the incidence of catarrhal conditions at the time when these readings were taken would have been of interest.

Eastbourne.

Eastbourne has a relatively small number of children in elementary schools, but the percentage of attendance is fairly high—nearly 92 per cent. The percentage of defects is close to the average for the whole country. It is noted that visual defects are the only conditions which have not been proportionately reduced, and an apparent increase of such defects has been found in other parts of the country. The only condition likely to be affected is myopia, and even here, says Dr. J. Kerr in his recent standard work on "School Vision," "it is quite impossible to say how much school contributes quantitatively to the aggravation of the condition of myopia, possibly 50 or 60 per cent. would be a full estimate, but these eyes are not originally made myopic by school"—i.e., school conditions are not the primary cause. Those familiar with the conditions in the schools of to-day will not readily believe that such conditions are responsible.

The physique of the children seems to be distinctly good. Dr. W. G. Willoughby points out that they are above the standard heights at all ages and above the standard weights at all ages except in the 12-year old group. The Eastbourne children are generally taller and heavier than they were in 1908, the difference in height often amounting to 1½ inches or more and in weight to 3 lb. or more. It is suggested that the improvement "cannot be dissociated from the child welfare work, since it is particularly marked in the younger children." The attendance of parents at routine inspections was poor, 48·4 per cent., and there are other indications that they are not fully coöperating—e.g., there were 304 cases who failed to attend the dental clinic this year; out of these, it is true, 108 promised to obtain private treatment, but experience shows that the value of such a promise is not always good.

The arrangements for treatment are fairly extensive, and there are nine different clinics, including an unofficial and voluntary orthopaedic clinic which we hope will become permanent. There is a special mental deficiency school and an open-air school, where much attention is given to the more serious cases of malnutrition.

Leamington Spa.

Dr. W. L. M. Goldie's report, for the most part, consists of a series of statistical tables. There are several points of interest which could have been elaborated to the benefit both of the medical practitioner and the layman. Leamington would seem to be fortunate in its small incidence of infectious disease, and no school closures were necessary on account of infectious outbreaks. The percentage of vaccinated children in the elementary schools has considerably diminished; 65 per cent. of these children are unvaccinated. It is interesting to note that as the children attain the leaving age there is a progressive increase in the number of vaccinations. In the secondary schools there is a much higher percentage of children vaccinated; only 32 per cent. of boys and 33 per cent. of girls are unvaccinated. The number of defects found at routine examinations is surprisingly small.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 30TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 88; scarlet fever, 1572; diphtheria, 697; enteric fever, 60; pneumonia, 1007; puerperal fever, 52; cerebro-spinal fever, 13; acute poliomyelitis, 4; encephalitis lethargica, 71; dysentery, 2; ophthalmia neonatorum, 118. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 48 from the number for the preceding week.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 76 from measles, 14 from scarlet fever, 71 from whooping-cough, 27 from diphtheria, and 48 from influenza. In London itself the deaths from influenza numbered 6, from whooping-cough 10, and from diphtheria 8.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. M. Ferguson to be temp. Capt., and relinquishes the rank of Capt.

Lt. H. I. Clapperton, late Ind. Army, to be temp. Lt. whilst employed as a Dental Surg.

W. G. Bradbeer to be temp. Lt. whilst empld. as a Dental Surg.

MILITIA.

Capts. to be Majs.: F. G. Foster, W. E. Elliot, W. W. Wagstaffe, C. Atkinson, H. K. Ward, and H. W. Maltby.

TERRITORIAL ARMY.

Maj. D. Dougal to be Lt.-Col. and to command the 12th (2nd Western) General Hospital, vice Lt.-Col. J. H. Ray vacated on completion of tenure.

ROYAL AIR FORCE.

R. F. G. Dickson is granted a short service commission as Flying Officer for three years on the active list.

Flight Lt. J. A. Quin is transferred to the Reserve, Class D2.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. Boulton to be Col.

Capt. Jyotish Chandra De to be Maj.

Lt. W. H. Critien to be Capt.

The King has approved the relinquishment of his temporary commission by Lt. Ragunath Balkerishna Chandrachud.

Col. A. A. Gibbs, I.M.S., has been appt. Hon. Physician to the King, Ind. Mil. Forces, vice Maj.-Gen. J. Jackson, I.M.S. (ret.).

Col. E. L. Perry, I.M.S., has been appt. Hon. Surgeon to the King, Ind. Mil. Forces, vice Col. F. Wall, I.M.S. (ret.).

OVERSEAS NURSES' MEMORIAL.—As a memorial to the nurses of the Overseas Nursing Service who died in the war, a nurses' home is to be built in connexion with the Elizabeth Garrett Anderson Hospital. In aid of the appeal fund Lady Burnham recently opened a replica of a modern operation theatre at the British Empire Exhibition. The Memorial Fund Committee includes the High Commissioners for Newfoundland, Canada, Australia, and New Zealand. The Overseas Nurses' Memorial Exhibit will be found in Bay 16, Avenue 6, in the Palace of Housing and Transport at the British Empire Exhibition, Wembley. Souvenir bricks can be purchased for 1*s.* each. Donations may be addressed to Lady Dufferin and Ava at the hospital, 144, Euston-road, London, N.W. 1.

LONDON HOSPITAL.—Mr. Bernhard Barron has given £10,000 for the erection of a new pathological department. The present department is entirely inadequate—five or six men are doing difficult research work in one room. A gift of a similar amount has been made by Mr. and Mrs. Williams for the establishment of an Owen Williams Research Fund, named after their son, who died in 1914. The contract, amounting to nearly £40,000, for the erection of the new hostel for resident doctors has now been let, and the consultative children's department is to be enlarged and improved, a new member being appointed to the honorary staff as a specialist in children's diseases. When this has been done it will be a consultative centre for all the children's welfare departments in the East End. There are still 101 closed beds in the hospital.

INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.

Visit to London, June 2nd–6th, 1925.

President—H.R.H. The Duke of York, K.G.

On Thursday, June 4th, the series of brief introductory lectures was continued in the morning at Wigmore Hall.

OPERATION IN GASTRIC AND DUODENAL ULCER.

By James Sherren, C.B.E., F.R.C.S.

It is well for surgeons to pause from time to time and ask themselves why they continue to treat certain conditions by operation. Are they convinced from their results that this procedure is the best in the interests of the patient and that it is the quickest, safest, and most efficient method of relief? This is particularly needful when dealing with disease in the abdomen. In acute abdominal catastrophes there can be no doubt that operation at the earliest moment satisfies these criteria. But I should not like to say that it is so with all abdominal disease or so-called disease. To take common examples, I feel sure that among those with the widest experience there is much less operating for such conditions as "chronic appendicitis" and much less removal of the appendix on the chance that it may relieve obscure abdominal symptoms. I am not among those who say this disease is a myth, but it is not as common as was at one time supposed. There is, however, no operation that will give greater relief than removal of the appendix when its disease is causing symptoms. But this is a difficult subject. I would also mention the diminution in the number of cases operated on for the relief of "intestinal stasis." We have learnt by our failures, and also by those of others. The percentage of cure in many patients with these labels is too low.

When Should We Operate?

I intend to devote the short time at my disposal to considering chronic ulcer of the stomach and duodenum along these lines. If we think that operation satisfies what I have just laid down, then, whether the operations we are doing meet all the requirements —that is, if they bring about cure with a minimum of risk—this question can only be answered satisfactorily by those who have a systematised follow-through of patients. This I have had from the first in dealing with this class of case and see or hear from all at intervals during the first year, yearly up to three years, then in alternate years. In this way it is possible to compare the result obtained by various methods and to improve these where necessary.

The problems of treatment of duodenal are different from those of chronic gastric ulcer, but I would emphasise as common to both—no surgeon should recommend operation in the absence of complications until medical treatment has failed, and this medical treatment should be directed not only to the internal lesion, which is an end-result, but towards dealing radically with its cause, so far as we can see at present any infective focus that may be met with. I particularly allude to infection from teeth, naso-pharynx, and tonsils. How common it is to have patients sent to us after suffering for years from symptoms suggesting ulcer and find septic conditions in association with the teeth. I would, however, impress on you that dental treatment to be effective must be carried out in the early months of the disease, and that after the lesion is once established removal of the focus will not cure it. But it must always be done prior to operation, not only to minimise the operative risk, but to prevent the development of fresh ulcer in the region of the anastomosis.

We must all have known delay in submitting the patient to operation lead to that procedure being carried out too late because carcinoma has supervened or lethal hæmorrhage; this delay is sometimes due to an undue reliance on the efficacy of dental extraction and valuable time lost. Sometimes the patient is X rayed with a negative result; in others this is not carried out, but a definite opinion is given that removal of all his teeth will cure his condition. This is done, the patient waits for the promised cure only to find that the carcinoma has become inoperable or some other lethal complication ensues.

If efficient medical treatment fails to cure or relapse occurs we should operate in both conditions. I am firmly convinced of the inadequacy of medical measures and of the impossibility of it being carried out for more than one course in the majority of patients with whom we have to deal. If the patient with duodenal ulcer is willing to put up with the discomfort of the attacks and can cut them short, as is usually the case, by rest in bed for 48 hours and light diet, should we urge operation? My answer is, most emphatically, yes. The more I see of cases of duodenal ulcer, the more dangerous do I consider the condition. We should not wait until signs of pyloric stenosis supervene—if the patient lives so long by escaping the twin dangers of hæmorrhage and perforation.

What Operation Should We Do?

In the hands of a surgeon used to abdominal work operative is the safest form of treatment. But what operation? It is rarely that we take up a surgical journal without seeing new operations urged for the cure of duodenal ulcer, many of them procedures that must, in average hands, carry with them a high death-rate, and some of which remove large portions of the stomach, a mutilating procedure, and to me a repellent one. I allude to duodenectomy with its technical difficulties and to wide partial gastrectomies. Neither of these operations is a guarantee against secondary ulceration; I have known it occur after both, and both carry a death-rate at least treble that of simpler, and I consider as efficient procedures.

Gastro-jejunostomy will bring about the healing of all duodenal ulcers except large posterior ones adherent to and eroding the pancreas, and even these sometimes heal. The ulcer does not recur if the new opening remains patent, which it does unless there is marginal ulceration. In a large experience of second operations, on patients of my own and other surgeons, I have never found the original duodenal ulcer unhealed except in the case I have just mentioned. I consider that we have solved the question of what will bring about healing of the original ulcer; our problem is to prevent ulceration in the region of the anastomosis and our whole efforts should be devoted to this problem, which is not insoluble, while our medical and pathological colleagues are busily engaged in discovering means of preventing the occurrence of chronic ulcer and so rendering surgery unnecessary.

But to bring about healing the gastro-jejunostomy must be efficient. It should be posterior, vertical, extending from the lesser to the greater curvature, and situated on a line just to the right of the cardiac orifice, the suture material used being catgut. I cannot wonder at dissatisfaction being expressed with the operation, carried out as I have seen it on reopening the abdomen, small, horizontal, and near the pylorus. If by reason of obliteration of the lesser sac by adhesions it is unwise and impossible to use the posterior surface of the stomach, I bring the jejunum without a loop through the transverse mesocolon and gastrocolic omentum to the anterior surface of the stomach. In those cases in which the mesocolon is shrunken and adherent or loaded with fat it may be unwise to do the usual trans-mesocolic operation. We should remember that post-operative vomiting is the result of obstruction to the anastomosis or its limbs. We should avoid any manipulations here likely to produce adhesions or narrowing of the opening in the mesocolon. In these cases I do an antecolic short loop operation to the posterior surface of the stomach. I take the jejunum just beyond the flexure, bring it in front of the transverse colon, and unite it vertically to the posterior surface of the stomach. Both these operations have given results nearly as good as the ideal one.

In the uncomplicated case I do not consider the ulcer itself should be treated. In ulcers that have perforated into the peritoneal cavity or in which the gall-bladder closes the perforation, I suture it vertically so as not to narrow the pylorus. In recent hæmorrhage I destroy the ulcer with the cautery and suture the opening in a similar manner. I have entirely given up infolding the ulcer; it is almost impossible to do this without narrowing the pylorus. The ulcer heals readily without it and I look on pyloric exclusion as a *predisposing* cause of jejunal ulceration, as it prevents efficient lowering of gastric acidity in many instances. The whole abdomen should be searched for other disease, particularly in the gall-bladder and appendix.

This operation in my hands brings about *cure* in at least 90 per cent. of the cases with a death-rate of less than 1 per cent. Similar results are obtained in your clinics. Is it therefore worth while to carry out extensive procedures when a simple operation brings about results such as these? Of the seven or eight that cannot be called cures, one, perhaps two, may develop secondary ulcers, the remainder may have vague complaints of discomfort, such as we all see even after partial gastrectomy.

In my experience after operation on these lines, if the patient remains well for two years he does not develop secondary ulceration. But the patient must have remained well—that is, there must have been no complaint of pain or discomfort after food. He must have had perfect health. These are the 90 per cent. who do not develop symptoms. It follows, therefore, that the statement that I have so frequently read, that the longer after operation these cases are reviewed the less numerous the cures, is incorrect. In the days in which silk and thread were used it is conceivable that symptoms due to secondary ulceration might appear much later when the suture was working its way out.

My experience of gastro-duodenostomy does not lead me to adopt it as a routine. I only employ it in rare instances where there is marked atony of the stomach together with a dilated duodenum in patients whose gastric acidity is not excessive. In my hands it has not brought about what I consider to be a sufficient lowering of gastric acidity and it does not protect against secondary ulceration. As a result of my experience I consider the surgical treatment of chronic duodenal ulcer not only the safest, but the quickest and most efficient method of cure.

With regard to the choice of operation in chronic gastric ulcer, we have here another danger to face, that of the development of carcinoma, and I consider it quite legitimate to mention this when discussing operation with the patient, so that we have additional reason for holding operation the safest procedure. It is, of course, impossible to be dogmatic, but I have found that in at least 25 per cent. of my specimens of carcinoma of the stomach removed by operation there was evidence of preceding simple chronic ulcer. Among specimens removed by partial gastrectomy as simple ulcer without definite evidence of malignancy, but were removed on account of their size, carcimona was discovered in the edge in 6 per cent. I am convinced that chronic gastric ulcer is a predisposing cause of carcinoma.

What I have said about operation for duodenal ulcer applies here also; gastro-jejunostomy will bring about the healing of all free simple ulcers when it is done to their cardiac side, but it must be done here, if it cannot the lesion is not suitable for treatment by this method, but should be dealt with by partial gastrectomy. I have reoperated on many patients in whom gastro-jejunostomy had failed to bring about a cure and found the new opening had been made distal to the ulcer. Gastro-jejunostomy done in this way will never cure gastric ulcer.

Small mobile ulcers can be treated by gastro-jejunostomy alone, or in addition destroyed by the cautery. Large indurated ulcers, those eroding the pancreas or liver, should be treated by partial gastrectomy, the former because of the impossibility of saying if they are simple or have become malignant, the latter because we know that many of these do not entirely heal as the result of gastro-jejunostomy alone. I have entirely given up excision combined with gastro-jejunostomy. It has, in my opinion, no advantages—if I think the ulcer should be destroyed I do it with a cautery. If it is too high for gastro-jejunostomy to be carried out to its cardiac side, excision and gastro-jejunostomy is useless; the ulcer recurs in the scar which will be on the cardiac side of the new opening.

I would plead that gastric ulcer be not treated on stereotyped lines—every case by partial gastrectomy—successful operation though it may be, but one that must by its very nature have a higher death-rate than gastro-jejunostomy and may, after years, have a deleterious effect. Let us treat them with an open mind, remembering the danger of malignancy. I am convinced that a simple chronic gastric ulcer heals as readily after gastro-jejunostomy as does duodenal ulcer. It may be said that there is a danger of carcinoma developing in the scar of a chronic gastric ulcer. If this be so, which I very much doubt, it is a very remote one, and I am sure the risk is more than counterbalanced by the increased death-rate of partial gastrectomy—more would die from the operation than from late malignant development.

In an extensive experience of gastric operations I have never seen the late development of carcinoma after gastro-jejunostomy had been carried out for a small mobile ulcer on the lesser curvature. The cases in which I have seen it, and they are rare, were in those which I now treat by partial gastrectomy and in cases in which for some reason although this was indicated it could not be carried out.

Conclusion.

I would urge, as far as possible, conservative treatment of lesions, believing that any additional cures that might be obtained, which I personally deny—as all cases of partial gastrectomy do not regain perfect health—would be more than wiped out by the greatly increased death-rate. I do not consider that the late results of partial gastrectomy surpass those of gastro-jejunostomy. Minor complaints, occasional discomfort, and vomiting are met with in 7 or 8 per cent. of these. But gastro-jejunostomy is an operation perhaps above all others that needs to be carried out with thought and its site carefully chosen. Done in the way I have described, it is an operation that seldom disappoints either the patient or the surgeon. It is the result of my experience that operation is still the line of treatment to be advocated with these diseases.

CANCER OF THE LARYNX.

[ABRIDGED.]

BY SIR STCLAIR THOMSON, M.D., F.R.C.P.

IN 1924 more than 50,000 people died from cancer in England and Wales, said Sir StClair Thomson, and the number of victims increases yearly by about 1700. Cancer of the larynx is a particularly interesting subject of investigation. First, because certain manifestations of it yield results in the way of lasting cure which are not surpassed in any other internal organ of the body: and, secondly, because in another form laryngeal cancer is well-nigh hopeless. While the speaker had been able to publish the records of lasting cure in 80 per cent. of intrinsic cancer, Mackenty questions "if extrinsic cancer will ever be amenable to surgery." Before the war, German teaching had perhaps a too preponderating influence on the other side of the Atlantic. Now laryngo-fissure undoubtedly owed its present position to the work of British surgeons ever since the early days of Durham, Butlin, and Semon.

A clinical description, with lantern illustrations, was then given of the manifestations of both intrinsic and extrinsic cancer. With regard to the latter it was pointed out that it is not always necessary to remove the entire larynx simply because there was a growth somewhere at its upper orifice or its outer surface. In fact, extrinsic cancer of the epiglottis, the aryepiglottic folds, and the post-cricoid region can sometimes be more successfully dealt with through a lateral pharyngotomy (as shown by Wilfred Trotter) than by the mutilating operation of complete laryngectomy. Cancer in the neighbourhood of the sinus pyriformis is seldom operable.

Complete laryngectomy is much more successful nowadays both as regards operative mortality and ultimate results for the good reason that it has been almost entirely abandoned for extrinsic cancer. It is now employed simply in those cases of intrinsic cancer which are too extensive to be dealt with by laryngo-fissure. But it will become increasingly less frequent as we progress in recognising epithelioma of a vocal cord more promptly and removing it by splitting the larynx. This recognition depends on teaching the public and the profession that any hoarseness, persisting for more than three weeks, should demand expert investigation. Further details in the methods of diagnosis were then given and illustrated.

The technique of laryngo-fissure was illustrated on the screen and temperature charts and specimens were shown. Four patients on whom laryngo-fissure had been performed eight, seven, six, and five years ago were then exhibited. Three of them belong to the working class; they are all able to earn their living and all had a good, rough, strong voice. Figures were also submitted showing a permanent absence of disease in 80 per cent. of cases. The results were indicated in another way by the statement that of 55 cases operated on before 1922 for intrinsic cancer of the larynx no less than 40 of them were alive and free from recurrence three years or more after the operation. Out of 66 cases only 10 had died from local recurrence. The rest had succumbed from other causes.

FUNCTIONAL NERVOUS DISTURBANCES IN CHILDREN.

By H. Charles Cameron, M.D., F.R.C.P.

Not without appreciating the boldness of the proceeding I am going to ask you, a gathering of scientific men, for a moment to turn your back upon the laboratory and the operating theatre and to come with me into the nursery life of some ordinary household, there to study the origin of certain common abnormalities of conduct in the child—to inspect, as it were, the very growing point of all neuropathy in the forcing house of the nursery. It is a study no doubt remote from the particular medical interests of many of you. Yet if we are not all particularly concerned as physicians with the study of childhood, as parents at least not a few of us have a very direct interest. For indeed the nursery is a place where we all meet upon common ground, parent, pedagogue, priest, pædiatrist, psychologist, and if the part played by the physician, as pædiatrist or as psychologist, is of supreme importance it is because he alone has knowledge of the full development in adult life of psychopathic disturbances and because he alone is able to appreciate the earliest deflections from the normal and to isolate from the tangle of forces acting upon the child that which is especially responsible for some particular disturbance. For such a task the wider outlook of the physician is very necessary. There is, indeed, a close resemblance between the abnormal conduct of the unstable child and the abnormal conduct of the insane, between the symptoms resulting from the functional weakness of the immature brain and symptoms directly due to degeneration or disease. In ascent and in descent, in development as in deterioration, the same country is traversed and we catch glimpses of the same scenery.

Thus it is clear that if we are to learn anything of the functional nervous disturbances of children we must pursue our investigations in the home. As with the insane, the conduct of the restless nervous child is at its worst in the intimate surroundings of the home. Let the offender be removed to an institution, an asylum in the one case, a hospital or a school in the other, and how great and immediate is the improvement! In the hospital, indeed, we may learn much of the physical processes of disease, of the child itself very little.

Maternal Traction.

In our visit to the home the first and most important object which we shall there encounter is no less a person than the mother, a being possessing the most amazing power over every action and every thought of her child. It is hardly possible to exaggerate the immensity of this power of maternal traction exercised consciously or unconsciously all day long. No doubt children differ very much one from the other in what we ascribe to inheritance, in temperament, in disposition, in ability. Yet that which is inherited is in the main a variation in the susceptibility in the degree of reaction to the influences of environment. With some children gross faults of management upon our part produce but little disturbance, with others the slightest mistake provokes its own reaction in the conduct of the child. The dependence of the conduct of the child upon its mother is doubtless at its greatest when the mother is an ardent mother, concentrating upon her single child or small family all her interests and all her thoughts. The contact becomes so close that it comes about that whatsoever the mother says of her child, thinks of him, above all, fears for him, that he tends to become. The child is quick to get ideas as to what is characteristic of himself and personal to himself. Yet he has no power of self-analysis. He judges of himself, for the most part, by what he sees in his mother's eye. The difficulty is greatest, I think, for the mother of an only child. All other interests are apt to go by the board and she settles down to an agitated contemplation of the wreckage wrought in the child by her own too great apprehension.

For in whatever way we may define maternal competence it is something very closely associated with maternal self-confidence. The response of the dominating egotistical child to conscientious yet timid and uncertain handling, I have described in a word borrowed from the literature of the alienist, *negativism.* We all know the negativistic child. To urge him to proceed downstairs determines a rush to the top of the house; dressing, equally with undressing, is resented with tears and struggles. If his mother carry him he desires to walk, if he is set to walk he desires to be carried. Negativism of this sort grows only in response to a certain type of management. It does not appear in the children of parents who are strong-minded and confident of themselves, who demand and expect obedience, who never contemplate the possibility of refusal or resistance. Nor, I think, does it appear in the children of those delightful mothers who never appear to bother even when the children habitually fall downstairs or climb with their muddiest boots over the drawing-room furniture. Negativism is the response of the child to a fault to which we are all prone as parents, the repeated and persistent attempts to secure control and the repeated and persistent failure to achieve it. Whenever traction upon the child is too obvious and too constant, yet in insufficient force, the child is forced into a posture of opposition, forced to make strain and to pull in the opposite direction.

The Force of Negativism.

Let us examine the part played by this force of negativism in the production of some of the common disorders of conduct in children. As among the insane, a persistent refusal of food, a veritable anorexia nervosa, is one of the commonest difficulties encountered in the management of the nervous child. It is instructive to note that among the poor, where food is apt to be short, the disorder is something of a rarity. The mother cuts off the hunk of bread, "That's all you're to have," says she; "I want some more," says the child; "You can't have it," says the mother. Among the very poor the opposite fault—shall we call it bulimia?—is the rule. When food is haggled over and doled out, the restless child is apt to develop an apparently insatiable hunger and to clamour all day for its satisfaction. I had in my ward last month a bright clever little girl of 6 from a cottage in the country. She was sent to me with the suggestion that her great polydipsia and polyuria were evidence of diabetes insipidus. Her life, indeed, was one long hunt for fluid. The mother told us that she had purloined and drunk two bottles of her father's stout, as well as two bottles of medicine which she found in the house. The precautions taken to ensure that she had no access to fluid were prodigious. In the ward, with a cup of water at her bedside, polyuria and polydipsia both disappeared within a few days. I understand that among a few of the least balanced adult minds in the United States prohibition has produced a reaction not very different from that encountered in this little child.

But in the nurseries of the well-to-do the common fault is over-persuasion. The child is urged, entreated, implored to take food. Sometimes, and it always makes matters worse, force is used and a strong-minded woman with uplifted spoon endeavours unsuccessfully to administer the prescribed amounts. Often the only articles of food for which the child shows any liking are those which the mother does her best to withhold from the conviction that they are unsuitable pabulum for a young child, cheese, pickles, and the like. It is always the very foods which the mother most eagerly desires the child to take that are most persistently refused. Sometimes when the struggle is at an end and the cloth removed, the child will astonish everyone by demanding food, or he may descend from his chair—in which he has refused to taste a morsel of the proffered meal—to scavenge greedily for crumbs upon the floor. Two mothers told me on the same day that they really thought that the best meal that their child made in the day was when with a parcel of broken bread they proceeded to an expedition to feed the ducks in the park. One mother had even taken to including in the parcel some nutritious pieces of brown bread and butter in the sure hope of their consumption by the child.

Successful Treatment by Judicious Neglect.

With anorexia nervosa of this sort, one treatment alone is successful. The mother must hide from the child her insistent desire that he should eat. The suggestion with which the food is proffered must be altered. The emphasis may be laid upon the fear that excess may be taken. Helpings must be ostentatiously halved. Only after a proper show of surprise and reluctance is the second half conceded. One day a boy was brought to me from the North of England. Always a poor eater, for some weeks I was assured that he had taken nothing but a few biscuits. The negativistic element was easily discernible in this child and when I explained my point to the parents, the father eagerly corroborated it. The boy, he said, was sick in trains, as many such children are. He was told, therefore, that he must not come into the restaurant car. He at once said that he felt very hungry. By insistence he got his own way, but for fear of the dreaded train-sickness his mother gave him the smallest of helpings, conceding the second helping with the greatest reluctance. As a result of the alteration in the parental attitude he then and there ate such a meal as he had not taken for years.

In the difficult question of nursery constipation, too, it is possible to discern the large part played by the negativism of the child. No doubt it is right and wise that the child's bowels should be open daily. The best way to help a child to such a desirable achievement is to take great and obvious pleasure in his regularity to convey to him the conception of himself as a small person of whom it is characteristic that his bowels are always open without fail. The direct appeal, the insistence, the agitation openly displayed when failure results—not open yesterday and to-morrow will be the third day—produces in young children a distaste and a spirit of opposition to the whole proceeding. The attempt to get the child to go to stool may produce a display of negativistic resistance comparable to that shown at meal-times or at bed-time. Such children have even been brought to me with the suggestion that there exists an anal fissure or some other cause for pain upon defæcation.

The diagnosis of this common pseudo-constipation may be supported by other observations. The subject of it is likely in his daily life to show many other instances of his tendency to negativism. Laxative drugs, in general successful enough, are here quite without effect. Only when a dosage sufficient to produce diarrhœa and perhaps actual incontinence, is the opposition and resistance overcome. It may be clear that the constipation varies in severity according to the person who is in charge of the child. A new management, for example, determined to overcome it, always produces an exacerbation. A visit to the seaside, with diversion of thought and concentration upon new employment and new surroundings, often brings temporary relief. Constipation of this sort is always said to produce fretfulness and bad conduct. Whether that is a likely result of true constipation I do not know, but it is clear that fretfulness and nervous unrest manifest themselves in an increase of negativism.

Stereotyped Movements.

In a second group of cases, of very different nature and origin, the disturbance is also perpetuated by the determined efforts of the parents to prevent it and the consequent opposition of the child. In infancy all children are prone to perform certain stereotyped movements, provocative of certain sensations which by much repetition have become pleasureable and soothing. Thumb-sucking, head-banging, thigh-rubbing or infantile masturbation are good examples of the class of movement to which I refer. As the level of the intellectual processes rises, as memory and imagination awaken, as the child lies in bed occupied in the recollection of yesterday's happenings and the anticipation of to-morrow's, these habits and these joys should be forgotten. It is very obvious that they are often kept in being by the concentration of the mother's mind upon them and by her persistent efforts to stop them. They cease only when they are forgotten. The attempts to forbid and prevent serve only to keep them in the fore-front of consciousness. The mothers of all children in whom thumb suction persists for an unduly long time have in common that they are immeasurably distressed by the habit and determined to stop it. A little girl of 4 was brought to me for inveterate thumb-sucking, which had survived much smearing of the offending digit with foul-tasting herbs, the use of a protective metal cage, rewards, punishments, and entreaties. I suggested that the mother should insist upon routine thumb suction being practised by the offender three times a day for ten minutes, on the principle that if a child's chief delight, shall we say the spinning of his top, is ordered regularly as a routine with sufficient peremptoriness, its attraction will promptly cease. In this case the thumb suction ceased within ten days.

In thigh-rubbing or infantile masturbation, which, because of its implication of the sex organs causes even greater distress to the parents, the ill-effects of elaborate efforts to foil and restrain, are even more apparent. The worst case of masturbation that I know of was cured by the accident that he developed an acute appendicular abscess. For six weeks he was very ill with general peritonitis. All thoughts of the inveterate habit were absent from his mind and from the minds of those in contact with him as he fought for his life. All attention, his own and other people's, was concentrated on the daily dressing. If in infantile masturbation preventive apparatus must be used, and there are a few cases in which it is difficult to avoid its use, I think that no expenditure of trouble is too great to prevent the child appreciating the purpose for which the restraint is employed. The child may think that it is worn to make the legs or the back straight, but let its real purpose be hidden. Otherwise the use of the apparatus rivets the attention upon the habit so that its ultimate removal carries with it almost the certainty of relapse. Of masturbation in older children, I am not, of course, at the moment speaking.

These few examples I take to illustrate my contention that in the nursery and in nursery management there is a wide field for the practice of an elementary form of psychotherapy. It is clear that it is through the mother and by means of her alone that we can control the disturbance in the child. We need not offend her by any appearance of fault-finding. Disturbances such as we are considering do not commonly occur in the child of a woman who is not an ardent mother. It is easy to show her that in a hundred and one ways she has done nothing but good to her child. In this one point, inhibited by the urgency of her fears and anxieties, she has perhaps failed. If her understanding is convinced and her coöperation secured all will be well. She is possessed of powers over her child incomparably greater than another can exercise. She has proved that by the profundity of the disturbance provoked in the child. It is a question only how this great power can be utilised for good and not for ill.

Among other short introductory lectures on Wednesday, June 3rd, and Thursday, the 4th, there should be mentioned an address by Mr. T. P. Dunhill on Auricular Fibrillation in Exophthalmic Goitre; one upon the Heart in Influenza by Dr. Strickland Goodall, who spoke of his conviction that the ætiology of heart disease in this country was changing the almost universal attribution to rheumatism disappearing; and one by Dr. Gordon Holmes on Suprarenal Disease.

Sir Walter Fletcher, in an address on Medical Research in Great Britain, pointed out how often our fine research work had been impeded by lack of money, quoting the facts that Newton and Faraday had been endowed by official positions, while Darwin's personal wealth permitted him to carry on his work independently. He named as the four conspicuous statesmen who had contributed to the progress of scientific knowledge Henry VIII., who founded the Royal College of Physicians of London, and from whom the chairs of medicine at Oxford and Cambridge gained the title of Regius; Charles II., who founded the Royal Society; the Prince Consort, whose influence on the status of scientific institutions and scientific men had been far-reaching; and Mr. Lloyd George, who founded the Development Commission, the Medical Research Council, and the Department of Scientific and Industrial Research. Sir Walter Fletcher briefly explained the constitution and composition of the Medical Research Council, and concluded by a happy reference to the linking up of the scientific work of Great Britain with that of America, a fine example of this being the sums of money which the Rockefeller Foundation had spent in this country.

The last of these addresses was delivered by Lord Dawson, who took as his subject the Speed of Life and Disease, and spoke wisely on the possibility that the medical profession should become more an educational body, as a result of the public appreciation that psychological culture had claims equal to those of physical culture. He pointed out that to-day human progress had outstripped human adaptation, and drew a striking, almost biting, portrait of the leader of commerce attempting to obtain a few hours leisure, heading to a breakdown, while disguising his anxieties under the name of pleasure. He believed, he said, that society was adapting itself to the new conditions, but more consideration should be given to the mental and physical make-up of the individual, and he hoped that now that doctors, in directing the health of the community, were devoting attention to prevention as well as to remedy, that the selection of the proper career of young people would come more under medical guidance.

SOCIAL FUNCTIONS.

Honorary Memberships.

The President of the Inter-State Post-Graduate Assembly of America, Dr. Charles H. Mayo, during the week of their visit to London, conferred the Honorary Membership of the Assembly upon H.R.H. the Duke of York; H.R.H. the Duke of Connaught; Rt. Hon. Austen Chamberlain, Minister of Foreign Affairs; Rt. Hon. Neville Chamberlain, Minister of Health; Lord Dawson of Penn; Lord Desborough, Chairman of the Pilgrims' Society; Sir Humphry Rolleston, Bt.; Sir John Bland-Sutton, Bt.; Sir William Arbuthnot Lane, Bt.; Sir StClair Thomson, Sir William Hale-White, Sir Holburt J. Waring, Sir John Y. W. MacAlister, Sir George Newman, Mr. W. Girling Ball, and Mr. Philip Franklin.

The Guildhall Banquet.

More than 600 sat down on Friday evening at the Guildhall banquet given by the Assembly, to which a number of distinguished visitors had been invited. Dr. Charles Mayo took the chair and proposed the health of H.M. the King and the President of the United States, both of which were drunk with musical honours. Mr. Neville Chamberlain, the Minister of Health, proposed the Inter-State Post-Graduate Assembly, his theme being the general practitioner as educator. Dr. Mayo, in responding, said that where the general practitioner did his duty, medicine would stand high in that community. He envied England its Ministry of Health and its Board of Education, each with a Secretary of State of its own. (These speeches have been made the subject of a leading article.) The British Medical Profession was proposed by Dr. Hugh Cabot and Dr. Woods Hutchinson, to which Lord Dawson of Penn responded. The last toast was that of the English-speaking Nations, proposed by Sir W. Arbuthnot Lane and Sir StClair Thomson, to which Dr. Franklin Martin, Director of the American College of Surgeons, responded. At the conclusion of the banquet Dr. Mayo conferred the honorary membership of the Assembly on Mr. Neville Chamberlain.

Dinner to Dr. Mayo.

A complimentary dinner to Dr. Charles Mayo was given by the Section of Surgery of the Royal Society of Medicine on June 6th at the Hotel Cecil, London. Mr. Herbert Paterson, President of the Section, presided, and there were present, among others, Dr. and Mrs. Franklin Martin, Sir StClair Thomson, the Rt. Hon. T. P. O'Connor, M.P., Sir William and Lady Arbuthnot Lane, Sir Anthony Bowlby, Sir William MacPherson, Sir D'Arcy Power, Sir George Blacker, Dr. and Mrs. Hugh Cabot, Dr. Woods Hutchinson, Sir James and Lady Berry, Mr. Cyril Nitch, Mr. and Mrs. H. S. Souttar, and Mr. Swinford Edwards. Mr. Paterson, in proposing the health of their guest, reminded them that Dr. Mayo was the son of an Englishman, as his father was born at Eccles, near Manchester. The success of the Mayo Clinic, he said, was due to the combination of high professional skill, consideration of the best interests of the patient, and fully organised business methods. He referred to the versatility and modest lovable disposition of their guest, and emphasised the value of clinical congresses in cementing the bonds of friendship and good-fellowship between the great English-speaking peoples. Since the visit of our American friends in 1910 we were, he said, gradually becoming used to these friendly invasions, and he hoped that they would be continued. Dr. Charles Mayo, in his reply, paid a tribute to the work of his brother, Dr. William Mayo, and thanked the members of the Section of Surgery for their warm reception. Mr. J. C. C. Davidson, M.P., proposed "America and American Surgery," and Dr. Franklin Martin replied. The toast of "The Chairman," proposed by Sir James Berry, brought the proceedings to an end.

RECEPTION BY THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

In the afternoon of Friday, June 5th, the President and Council held a reception in honour of the American delegates and their friends in the Museum of the College, when Sir John Bland-Sutton, the President, delivered an entertaining half-hour address on the intriguing subject of the Psychology of Animals Swallowed Alive. His text occurred to him, he said, one evening after dinner, in the thought whether animals which swallowed their prey alive endured discomfort from the efforts of the prey to get out again. With regard to the story of Jonah in the whale, he had once thought a parallel of that incident could not be found in modern times, but he since discovered in the *Boston Post Boy* for 1771 an account, vouched for by eye-witnesses, of a sailor in a small whaling ship who had been taken into a whale's mouth, and had been eventually vomited up—"rather sick and dizzy, but alive." The lecturer then went on to describe the habits of a prickly fish with two powerful teeth used for crunching coral. This fish was often swallowed by sharks, and when swallowed was able to blow itself out to the size of a football, thus causing its host considerable discomfort—and worse, for with its powerful teeth it would gnaw its way right out through the shark's side. "What terrible agony," said the lecturer, "but what a just revenge!"

Another fish whose living meal often revenged itself was the "black swallower," the Chiasmodon. Its stomach was so distensible that it could swallow a fish much larger than itself. Putrefaction of too ample a meal sometimes preceded digestion, with the result that the gas-distended stomach brought the deep water Chiasmodon to the surface, where it could not live. Sir John Bland-Sutton then described several other instances of living meals, among fishes and snakes—of pike swallowing pike, of dogs consuming whole Alaskan frozen fish which were in ventro revived to activity, and finally of the adventures of a pet tree frog of his own. One story was of a snake which had swallowed a frog alive. The snake's owner laid the animal on a table to watch developments. Someone accidentally tapped the table, whereupon the snake jumped off and the interned frog was heard to squeak. At this the snake opened its jaws and ejected its meal, which, covered with slime, hopped away into safety. The lecture was greatly enjoyed by the guests, who recorded their appreciation in a very adequate manner.

A pleasant programme of music was discoursed throughout the remainder of the afternoon. The guests had the opportunity of inspecting the College museum and library, where many interesting old prints and portraits were on view and where a microscopical demonstration was staged.

DINNER WITH THE PILGRIMS.

The Duke of Connaught, as President of the Society, took the chair on Thursday evening, June 4th, at a dinner given by the Pilgrims at the Hotel Victoria, London, in honour of the medical visitors from the United States and Canada. The health of the American doctors was happily proposed by Mr. Austen Chamberlain, who disclaimed any connexion with a liberal profession, while acknowledging a profound debt to his professional advisers. He had, he thought, adopted a sufficient share of responsibility in matters of importance, so that it was an immense satisfaction to him to feel that his health was no business of his while he entrusted it to his medical adviser. In an eloquent conclusion, describing the progress made in the last generation in the study of tropical diseases, he coupled the name of Dr. Charles Mayo with the toast. Dr. Mayo, in acknowledging the happy feeling which had been engendered by the Royal welcome which had been extended to the Assembly in London, said that men from across the Atlantic had the same ideas as those that were found in the greatest city in the world, for they were of the same stock—a personal matter to himself whose family for 200 years had been buried in a Manchester churchyard and whose father walked a London hospital before deciding to make his way in America. Dr. Mayo then addressed the Duke of Connaught, Mr. Chamberlain, and Lord Desborough, the Chairman of the Pilgrims, and declared them honorary members of the Inter-State Assembly.

LUNCHEON TO DR. MAYO.

At an informal luncheon earlier on the same day, presided over by Mr. A. Webb-Johnson at the Middlesex Hospital, the connexion of Dr. Mayo with London, and especially with Middlesex Hospital, was brought prominently to notice, for at the luncheon there was exhibited to Dr. Mayo the portrait of his great uncle, who was a surgeon to the Middlesex Hospital 100 years ago, and was one of the founders of the medical school there.

A number of American doctors and friends attended a garden party in the square of St. Bartholomew's Hospital on Thursday afternoon, when the Great Hall, Hospital Dispensary, and the Medical College buildings were on view, and Sir D'Arcy Power gave a short address on the antiquities of the hospital and its neighbourhood.

The medical staff of the Central London Throat, Nose, and Ear Hospital entertained a party of 40 to luncheon at the Carlton Hotel on Tuesday in connexion with the visit of the Inter-State Post-Graduate Assembly of America, followed by a demonstration of special cases, operations, and lectures by members of the staff at the hospital.

THE BATEMAN APPEAL.

AS already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	465	18	0
A Grateful Patient	5	5	0
Anonymous	1	0	0
Dr. O'Sullivan	1	0	0
" Miles "	0	10	6
	473	13	6

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

PRESTON ROYAL INFIRMARY.—This hospital of 200 beds is to be enlarged by a new wing containing 72 beds, an additional operating theatre, and a laboratory, at a cost of £30,000.

BRISTOL MEDICAL SCHOOL.

ROYAL OPENING OF NEW UNIVERSITY BUILDINGS.

"At one time it was thought that a university town was the seat of a university and nothing else, and people would have seen something incongruous in the idea of a university being placed in a great commercial and manufacturing town like Bristol. But it has been the most characteristic feature in the modern development of higher education that the newer universities have been founded in busy and populous centres. I am convinced that this is in the best interests of both learning and business, and that the interaction of the two is stimulating and helpful to each other."

Medical Library.

Benedictio et claritas et sapientia et gratiarum actio, honor et virtus et fortitudo, Deo nostro in saecula saeculorum

University of Bristol: The New Buildings.

These words were spoken by His Majesty the King when, accompanied by Queen Mary, he formally opened the new buildings of University of Bristol on Tuesday, June 9th. The beautiful and dignified structure, of which we reproduce a drawing from the souvenir booklet published by Messrs. J. W. Arrowsmith, Ltd., is due to the munificence of the Wills family, and the occasion of the opening marks a notable event in the annals not only of the 16-year-old University, founded by a Charter from King Edward VII., but of the ancient city. In 1909 the University College of Bristol and the Merchant Venturers Technical College were merged into a new university, but incorporation of the medical school was not then made complete. As the result of the suggestions from the University Grants Committee and the Treasury, the teachers of clinical subjects in the medical faculty who had preserved a partial autonomy have now surrendered their proprietary rights to the University, and the whole medical curriculum comes under University management. The medical student of to-day in Bristol enjoys exceptional opportunities and advantages. The preliminary studies of chemistry, biology, and physics are carried on in some of the newest and most up-to-date laboratories in the kingdom. The chemical wing was built in 1911 and the new physics wing built and endowed by the late Mr. H. H. Wills is nearing completion. The Department of Physiology is situated in part of the wing by the Arrowsmith Tower, the tower which forms a striking landmark and characteristic feature of the new buildings. Above the physiological theatre and laboratories is the Department of Pathology. The new building contains a fine medical library, of which we reproduce an illustration, in which the separate libraries of the Royal Infirmary, General Hospital, the Bristol Medico-Chirurgical Society, and the University College are housed together. Although the medical faculty for Bristol University is of very recent creation, the Bristol Medical School was founded over 100 years ago. Its early history is sketched by Dr. J. A. Nixon in the current issue of the *Bristol Medico-Chirurgical Journal*, in which he tells how the project of founding a medical school in connexion with the infirmary was first considered in 1816. By 1830 various independent courses of lectures had been combined to form two recognised medical schools, the School of Anatomy and Medicine in Limekiln-lane recognised by the Apothecaries' Hall), and the Bristol Medical and Surgical School (recognised by the Royal College of Surgeons). Three years later these schools were amalgamated to form the Bristol Medical School. The inauguration of the new buildings will surely open a new era of opportunity for the study of medicine in Bristol. All the various authorities in Bristol responsible for the hospital management have taken up the most friendly and helpful attitude towards the University and its medical students, both undergraduate and post-graduate. The student has at his disposal 630 beds for the study of clinical material, divided between the Royal Infirmary and the General Hospital, and in addition 566 beds in the large modern Poor-law hospital at Southmead. The City Fever Hospital has a total of 271 beds, and there are opportunities to study tuberculosis at the Municipal Dispensaries of the Frenchay Park Colony for children. Further, students are welcomed at the small but well-equipped orthopædic hospital which contains 36 beds.

ROYAL FREE HOSPITAL:

THE FESTIVAL DINNER.

The Festival Dinner of the hospital was held on Tuesday, June 9th, in the Guildhall, London, E.C., by permission of the Corporation. Lord Riddell, President of the hospital, was in the chair, and presided over a very large company of guests of both sexes. The occasion was characterised by some good speaking, a spirit of general enthusiasm for the object of the dinner, and a substantial pecuniary harvest.

After the loyal toasts, the Rt. Hon. J. H. Thomas, M.P., proposed the Prosperity of the Hospital in terms of real eloquence. He started humorously by observing that, had it not been for a fatal accident which terminated its existence, the representatives of the Labour Government would have been present last year at the annual banquet at the Guildhall; he had arranged to deliver a really Imperialistic oration on that occasion, and though that speech could not be made he was grateful for the opportunity which Lord Riddell had given him of speaking in the Guildhall. He proceeded to draw once again the old picture of the pathetic position of the sick poor, but did so in new and vivid terms while testifying to the value of hospital work. The toast was replied to by the Chairman and Dame Louisa Aldrich-Blake. Lord Riddell said that it appeared that any self-respecting hospital that desired to raise money must either be falling down, or about to close many of its wards, or have a substantial overdraft at the bank. In the case of the Royal Free Hospital he admitted the existence of the overdraft, but was unable to say that the fabric was falling down or that the Governors were about to close any of the wards. On the contrary, he stated the building to be as solid as ever, while not only would no wards be closed, but the appeal that night was directed to obtain money to build new children's wards. He reinforced his plea for children by a quotation from a speech at a charity dinner made by Charles Dickens 80 years ago, and disclosed the magnificent generosity of Mr. Alfred Langton, "a fairy of Gray's Inn-road." Dame Louisa Aldrich-Blake, who was received with continued applause, spoke out of a long association with the hospital, upon its position as the seat of the London School of Medicine for Women, and took the opportunity of congratulating Sir James Berry, the senior surgeon, upon his recent knighthood.

The toast of the Guests, proposed by Dr. J. Walter Carr, was responded to by Lord Jessel and Mr. C. T. Cramp; and that of the Medical Profession, proposed by Sir Charles Wakefield, was responded to by Sir Humphry Rolleston and Sir Squire Sprigge.

The sum of £25,000 was raised at the dinner, including a donation of £5000 from Mr. Langton, and one of nearly £4000 from Lord Riddell.

"Audi alteram partem."

CLEAN MILK IN HOSPITALS.

To the Editor of The Lancet.

Sir,—In view of Dr. Chalmers Watson's admirable propagandism in connexion with supplies of clean milk, and the special article by Dr. Savage on the Milk-supply and its Improvement appearing in your columns, it appears desirable to put on record the Aberdeen position. In October, 1924, Aberdeen Town Council gave authority to have certified milk used in all the public health institutions of the city. These include the City Fever Hospital and Tuberculosis Hospital, Burnside Home for Mothers and Babies, Loch-street Home for Mothers and Babies, and the Charlotte-street Day Nursery. At the same time the town council authorised that certified milk only should be supplied to all mothers and children obtaining milk in their homes from the health department, and also to all tuberculous patients similarly receiving milk in their homes.

With a view to encouraging the production of certified milk, the Aberdeen dairymen have been informed that the town council contract will necessarily be divided among dairymen retailing certified milk. At the same time, producers of milk in the Aberdeen area have been assured that the health department will do everything in its power to assist them should they be prepared to supply certified milk. Thus, whenever a dairyman is prepared to supply certified milk, the public health department is prepared to analyse the milk samples twice weekly, free of charge, and to send results of the analyses, both chemical and bacteriological, to the milk producer for his guidance. The milk producers have also been informed that they will be given a period of some six months in which to adjust their production of milk, so that it meets the certified standard, without any interference from the health department apart from helpful advice. The milk producer who at present holds the Aberdeen Town Council contract for certified milk is using the bacteriological counts, as supplied by the health department, to form the basis of the bonus system on which he pays his workers. Thus the milk counts as sent to the milk producer are posted on a notice board every week at the two farms producing the milk for the information of the workers, and the workers receive a bonus to their wages descending in amount according as the count of the milk ascends from under 5000, under 10,000, under 15,000, &c., organisms.

When certified milk was thus introduced into Aberdeen some seven months ago, all the medical practitioners of the city were circularised, urging them to do everything in their power to get their patients to use certified milk in their households. The wide publicity given by your columns to the matter of a clean milk-supply is of the most useful description and will, I am confident, be productive of much good.—I am, Sir, yours faithfully,

J. Parlane Kinloch,
Medical Officer of Health, Aberdeen.
June 8th, 1925.

BAKER'S ITCH AND WORKMEN'S COMPENSATION.

To the Editor of The Lancet.

Sir,—Captain J. T. Ainslie Walker expresses the opinion that the industrial ailment "baker's itch" (baker's eczema) is attributable to the use of certain so-called "flour-improvers," and he quotes Dr. Prosser White as stating that this affection is unknown in France and the United States, where these additions to flour are forbidden. I have brought forward definite facts[1] to show that in at least one bakery potassium persulphate was the cause of the trouble.

---

[1] The Lancet, August 11th, 1923, p. 279.

It is stated by the trade that baker's eczema was not unknown in this country prior to 1911—the year in which persulphate flour-improvers were first patented —but it is obvious from the continually recurring interest in this subject that it is much more common now than formerly. I agree with Dr. White that "improvers" are not the whole story, but I cannot subscribe to his statement that "no improvers are used in the confectionery trade." Confectioners may not "add" improvers to the flour they use, but they certainly often use flour containing "improvers" added by the millers. It may be that the comparative immunity of the bakers in the United States and France is in part accounted for by a more general use of machinery, as distinguished from the handling of wet dough practised here in many small bakeries. Nevertheless, I am convinced that baker's eczema has arisen in this country, in known instances recorded by me, by reason of the employment of these foreign chemicals which have been added to flour. Such additions are, in my opinion, unjustifiable on any ground.

I am, Sir, yours faithfully,

ARNOLD ROWSBY TANKARD, F.I.C.,

June 5th, 1925. City Analyst, Hull.

COLLOIDAL KAOLIN.

To the Editor of THE LANCET.

SIR,—The authoritative statements of Sir Wm. J. Pope and Prof. John W. H. Eyre in your issue of May 30th add weight to the rapidly accumulating evidence regarding the curative properties of colloidal kaolin. Since you published my original paper (THE LANCET, 1923, i., 432) the medicinal use of colloidal kaolin has extended widely. The Kaylene Company (which prepared colloidal kaolin for medicinal use at my suggestion) is now producing four preparations: Kaylene, plain; kaylene saline (i.e., colloidal kaolin with saline aperient); kaylene mint (colloidal kaolin with oil of peppermint); and kaylene lax (colloidal kaolin with phenol-phthalein).

Experience is fully bearing out the claims I made for it, and while I have nothing essential to add, I desire to emphasise a few points: 1. Colloidal kaolin must be of guaranteed purity and sterility and in the finest attainable state of mechanical subdivision. 2. Colloidal kaolin counteracts the toxæmia which results from the ingestion of unsuitable food—i.e., food that is apt to decompose in a toxic bowel. It is unwise, however, to exploit this way of escaping the consequences of wrong feeding. Obviously the best results are to be obtained by taking colloidal kaolin while using the diet and régime most suited to the relief of stasis. 3. Liquid paraffin as well as colloidal kaolin is nearly always needed in stasis. 4. Colloidal kaolin should not be given—in the hope that it will cure—without first deciding by X ray investigation that no mechanical block (kink, controlling appendix, scar of an ulcer, or neoplasm) needs surgical treatment.

I am, Sir, yours faithfully,

Upper Wimpole-st., W., June 6th. ALFRED C. JORDAN.

BLOOD CHANGES IN SPRUE AND PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—I am sorry to have overlooked Dr. William Hunter's criticism in your issue of Jan. 31st, p. 255, of my calculation of colour-indexes (THE LANCET, Jan. 10th, p. 75). I can easily show that these objections are founded on a misunderstanding. I estimated my hæmoglobin values with the original hæmometer of Sahli, manufactured by E. Büchi at Bern. In all my publications the numbers under the heading "Hæmoglobin (Sahli)" are hæmometer degrees (Sahli), and not percentages; 80 degrees (Sahli) correspond to 100 per cent. hæmoglobin, which is normal. To get percentages one has to calculate them; 20 Sahli is equal to 20 × 100 ÷ 80, or 25 per cent. hæmoglobin. As in Sahli's first hæmometer the degrees gave the percentages; on the Continent the bad habit to speak of per cent. (Sahli) when hæmometer degrees (Sahli) of Sahli's new hæmometer are meant is still maintained. I hope this will do to elucidate the matter.

To understand how Dr. Hunter could find greater differences than 1/5, I re-calculated my indexes with the following result: Of my 18 indexes I found now for 11 the same value as in the blood tables in my article; for 3 a value of 0·01 higher or lower, for 2 a value 0·1 higher; and for 2 others a value of 0·03 and 0·07 lower than in the tables. Only the two latter re-calculations are in the advantage of Dr. Hunter's presumption that my indexes should be too high. The differences can probably mostly be explained in a different way in which the decimals are neglected in the calculations, and even if slight errors are made, these are too small to have any practical significance and do not affect the conclusions, which have to be drawn from my figures.

I trust that Dr. Hunter and the English reader will be satisfied with this elucidation and that I have convinced Dr. Hunter that I use the usual standards. In conclusion, I wish to thank him for having cured me from a bad habit.

I am, Sir, yours faithfully,

The Hague, June 6th. C. ELDERS.

POST-GRADUATE TEACHING IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—I was most interested in reading Dr. Margaret Balfour's recent letter (THE LANCET, May 23rd, p. 1104) as my own experiences in seeking post-graduate work in midwifery after the war, in 1919, were much the same as hers, both in London and at the Rotunda. Having graduated elsewhere, and desiring to see something of London's methods, I applied to the Fellowship of Medicine, but the obstetrician to whom I was referred from there received me unwillingly and advised me to return to my own medical school or else to go to Dublin, saying London could receive no new students. After various similar inquiries I wrote to the Rotunda contemplating six months' work there, but the nature of the tuition was such that I transferred from there when one month had elapsed, like very many other graduates recently demobilised. At the Rotunda the clinics were crowded with students, graduates, and large numbers of pupil midwives, the Master turning to the latter for a correct reply when this was not furnished by the particular graduate or student whom he questioned!

If greater facilities for post-graduate tuition and opportunity for work in obstetrics are provided here fewer doctors will go to Vienna and Paris and other continental schools, as they at present do.

I enclose my card, and am, Sir, yours faithfully,

June 6th, 1925. M.B., Ch.B., L.M.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—May I ask you to publish a disclaimer of my having been in any way responsible for the inspiration and publication in the current issue of the *Ebbw Vale Weekly Argus* of a paragraph entitled "Doctor's Splendid Record: Two Medical Men Exonerated from Blame."

An inquest—held after the death of a patient from pneumonia supervening upon "radical operation" for inguinal hernia—was held at the instance of the deceased's relatives to establish the fact that the train of circumstances which led up to his death was the result of an accident—i.e., the original rupture. But when a death occurs after an operation there is wont to arise a suspicion that something went wrong with the operation—and the subtitle "medical men exonerated" suggests this view.

I simply mentioned the usual percentage of deaths after the "radical cure operation" to show that my average was well within the record.

I am, Sir, yours faithfully,

H. NEVILLE TAYLOR.

The Hospital, Ebbw Vale, June 3rd, 1925.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, JUNE 9TH.

TAXATION OF PATENT MEDICINES.

THE House went into Committee on the Finance Bill, Mr. HOPE (Chairman of Committees) in the chair.

Clause 2 provides that the additional excise duties imposed by Section 11 of the Finance (No. 2) Act of 1915 upon medicines liable to duty shall continue to be charged until August 1st, 1926.

On the motion that the clause stand part of the Bill,

Captain WEDGWOOD BENN complained of the way in which it was drawn. It was an elementary canon of taxation that the taxpayer should know exactly what, and upon what, he had to pay. The clause was the worst possible example of legislation by reference. It referred to the Finance Act of 1915, which in turn referred back to the Medicine Stamps Act of 1802, and that measure was related to the Tonnage and Poundage Act of Charles II. The Act of 1802 set out a schedule of medicines liable to be taxed. Giving examples of the medicines, he quoted the following: Asiatic bilious pills, Austin's chalybeate pills, Addison's re-animating European balsam, Clyde balsam, Guest's Welcome Guest powder, and Wheatley's ointment and fluid. The Act of 1812 revised the schedule and that was the last revision he could find. He asked if it would be possible between now and next year to look into this question, and to include in the next Finance Bill a clause, stating plainly what the taxes were and on what commodities they were levied.

Mr. W. GUINNESS (Financial Secretary to the Treasury) said that the first legislation on this subject was passed in 1783. Since then there had been repeated amendments. He admitted that it was not very easy for anyone to summarise the principles on which the duties were imposed. Speaking generally, there were three alternative tests of these preparations which were liable to duty. The first test was that they must be advertised or, in other words, recommended as a specific for some illness or disease. If they said that so-and-so's preparation cured headache, they were liable to duty, but if they said that such-and-such an ointment was good for the skin, and therefore not a specific for a disease, they did not come within that definition. The second test was that it should be secret, and the third was that it should be proprietary. The proprietary test covered most of the preparations that came under the old patent medicine duties. The codification of legislation on the subject was a matter into which he would like to look further, but it concerned the Ministry of Health rather than the Treasury. A few years ago a Select Committee inquired into this subject, but nothing was done as a result of their report. There were many more complicated forms of revenue collection, which were based upon a far more scattered legislative code than this particular patent medicine duty. Our customs legislation had not been codified for many years, but in view of the fact that it was working smoothly he did not think the House would see any cause to resist the retention of this clause. The duty was doubled in 1915 as a war tax, and was now yielding over £1,300,000, which was nearly three and a half times as much as before it was increased. That showed that the tax was useful from a revenue point of view, and it was not pressing hardly on any section of the population.

Sir A. MOND said that he did not admit that Mr. Guinness's statement about the customs was an adequate reason for not dealing with this matter. It was time that both questions were cleared up. This matter had nothing to do with the Ministry of Health. If the recommendations of the Patent Medicines Committee which sat some time ago were adopted it would be necessary entirely to alter the process by which these duties were levied. There were a large number of American patent medicines or mixtures being imported into this country. The importers of these foreign productions were given an advantage compared with those of British manufacture. He suggested that an expert committee should be set up to study the question.

Dr. HADEN GUEST said that the composition of most of these patent remedies was perfectly well known and were quite simple. Their vogue depended on the extent to which they were advertised. He thought that it was right that the law on the subject should be codified and brought up to date before the next Finance Bill was produced, and he hoped that would be done. If they reduced the law to a reasonable and intelligent code more attention might be paid to the demerits of some of these productions.

The clause was agreed to.

Progress in Housing.

Sir WILLIAM DAVISON asked the Minister of Health what progress had been made in the provision of houses during the past three months.—Sir KINGSLEY WOOD replied: During the three months ended May 1st last 21,674 houses were completed in England and Wales in connexion with State-assisted schemes, and 56,202 were in course of construction on May 1st. Particulars are not available as to the number of houses erected during the same period by private enterprise without Exchequer assistance.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S) EXAMINATION FOR MEDICAL DEGREES.

Honours.—John C. Barrett (*b*), St. Thomas's Hosp.; Richard A. Brews (*d*, *e*), London Hosp.; Charles P. Craggs (*d*), St. Bart.'s Hosp. and Durham University; William Evans (*d*), London Hosp.; Reginald S. Johnson (*a*, University Medal) and Frederick D. S. Poole (*a*), St. Bart.'s Hosp.; Mary E. Tyars (*a*, *e*), Univ. Coll. Hosp.; Iris V. I. Ward (*d*), London Sch. of Med. for Women; and Arthur J. Wrigley (*b*), St. Thomas's Hosp.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Harriet E. Acheson, London Sch. of Med. for Women; William L. Ackerman, London Hosp.; Francis G. Allan, St. Thomas's Hosp.; Harold G. Anderson, St. Bart.'s Hosp.; Doris M. Baker, St. Mary's Hosp.; Margaret A. Bannerman and Alison Elfreda M. Barnaby, London Sch. of Med. for Women; Philip C. Bennison, Guy's Hosp.; Dora M. Berry, London Sch. of Med. for Women; Thomas S. Blacklidge, Guy's Hosp.; Solomon Bloom, St. Bart.'s Hosp.; William G. Booth and Ralph Brooke, Guy's Hosp.; Hilda L. Byett, London Sch. of Med. for Women; John A. Carman, London Hosp.; Leslie I. M. Castleden, St. Bart.'s Hosp.; Edward H. P. Cave, King's Coll. Hosp.; Edith I. Clark, Univ. Coll. Hosp.; Harold G. Close, Guy's Hosp.; Doris M. Collins, London Sch. of Med. for Women; George E. C. Collis, Univ. Coll. Hosp.; Cecily D. Crosskey, London Sch. of Med. for Women and Birmingham University; Cedric K. David, Cecil H. Devereux, and Alfred C. M. Elman, Univ. Coll. Hosp.; Mary H. Elmitt, Barbara Finch, and Mary S. A. Foden, London Sch. of Med. for Women; Francis G. France, St. Bart.'s Hosp.; Ian W. Gallant, Univ. Coll. Hosp.; Florence M. Gamble, London Sch. of Med. for Women; Katharine A. C. Gillie and Arthur W. Grace, Univ. Coll. Hosp.; Geoffrey E. R. Hamilton, King's Coll. Hosp.; Alfred B. Hodgson, Birmingham University; Maurice W. P. Hudson, St. Thomas's Hosp.; Roland G. W. Husbands, Univ. Coll. Hosp.; Beatrice Jervis-White-Jervis, St. Mary's Hosp.; Ernest F. Johnson, St. George's Hosp.; Bertram H. Jones, St. Thomas's Hosp.; Horace Joules, Middlesex Hosp.; Noel E. ffarnwell Kemm, Bristol University; Victor J. F. Lack, London Hosp.; Muriel A. Lester, London Sch. of Med. for Women; Neville L. Lloyd, Guy's Hosp.; Alec McMillan, Birmingham University; Richard G. Maliphant, Univ. Coll. Cardiff and Univ. Coll. Hosp.; Bernard A. J. Mayo, St. Bart.'s Hosp.; Joseph H. Moore and Henry S. Morley, Univ. Coll. Hosp.; Marjorie Murrell, Josefine W. Nagel, and Elizabeth H. R. Newboult, London Sch. of Med. for Women; Margaret D. Nichols, London Hosp.; Helen E. D. E. Ornstein, King's Coll. Hosp.; William E. Rees, St. Thomas's Hosp.; Laura M. Rhodes, London Sch. of Med. for Women and St. Mary's Hosp.; Frederick T. Ridley, Birmingham University; John J. R. Robinson, St. Thomas's Hosp.; Sybil H. G. Robinson, London Hosp.; Edith M. Ross-Johnson and Frank E. E. Schneider, Univ. Coll. Hosp.; William G. Sears, Guy's Hosp.; Charles N. Smith, Univ. Coll. Hosp.; Sylvia M. T. Smith, Univ. Coll. Cardiff and Bristol University; Victor A. T. Spong, St. Bart.'s Hosp.; Nettie H. Stein, London Sch. of Med. for Women; Ernest V. Suckling and Glyde P. Tatton, London Hosp.: Catharine F. Taylor, London Sch. of Med. for Women; Ronald W. Thomas, London Hosp.; William R. Thrower, St. Bart.'s Hosp.; Mary M. Wickham, London Sch. of Med. for Women; Edward R. P. Williams, Univ. Coll. Hosp.; Edith V. Wood, London Hosp.; and Joyce P. Yeoman, St. Mary's Hosp.

King's College.—At the last meeting of the Senate of the University final approval was given to proposals of the Delegacy for extensions to the Department of Physiology. Building will be commenced at an early date and it is expected that the new rooms will be ready by the end of the long vacation. By the new building facilities will be provided for experimental research, a professor's room, and for the teaching of advanced practical mammalian physiology. Approval was also given for the establishment of two research studentships, each of the annual value of £100, while a sum of £50 has been set aside to meet the expenses of such research.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting of the Faculty held on June 1st the following were admitted (after examination) as Fellows of Faculty:—

John Gardner, M.D., Glasgow; Stanley Galbraith Graham, M.B., Glasgow; Chandiram Hassomal Primlani, M.B., B.S., London; James Hinton Robertson, M.B., Ch.B., Glasgow; and James Taylor, L.R.C.P. Edin., F.R.C.S. Edin., Glasgow.

Dr. T. S. Beauchamp-Williams, who was a Member of the last House of Commons and who contested Lambeth (Kennington) unsuccessfully last October, is standing as Labour candidate in the Eastbourne by-election, for which polling takes place on June 17th.

General Medical Council: Summer Session.—A penal case, the hearing of which was commenced on May 29th, was resumed on June 4th, and concluded on June 5th. The Council found the charges brought against the practitioner in question were not proved to the Council's satisfaction.

National Hospital for Diseases of the Heart. To-day, June 13th, at 3.45 P.M., the foundation-stone of this hospital's out-patient department extension will be laid by the Grand Master of the Order of Crusaders, assisted by several hundred members of the Order. At 2.30 P.M. a preliminary service will be held at St. Marylebone Parish Church, at the conclusion of which a procession from the church to the hospital will be formed.

David Lloyd Roberts Lecture.—The nomination for this annual lectureship, founded by bequests of the late Dr. David Lloyd Roberts, of Manchester, is alternately made by the Royal College of Physicians of London, the Medical Society of London, and the Royal Society of Medicine. This year the nomination is in the hands of the Royal Society of Medicine. The Council has invited Sir Arthur Keith, F.R.S., who has consented to deliver it at 1, Wimpole-street, London, on the afternoon of Monday, Nov. 16th.

Australian and New Zealand Medical Association in England.—The half-yearly dinner of this association will be held at the Trocadero Restaurant, Piccadilly, London, on Friday, June 26th, at 7.45 P.M. All visiting Australians and New Zealanders wishing to be present should communicate with the secretaries, Drs. E. T. C. Milligan and H. Bedford Russell, at 86, Harley-street, W. 1.

Glasgow University Club, London. — The annual summer dinner of this club will be held at the Trocadero Restaurant, Piccadilly, W., on Friday, July 3rd, at 7.15 for 7.30 P.M. The Right Hon. Augustine Birrell, K.C., LL.D., will preside. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the hon. secretaries, 1, Harley-place, London, N.W. 1.

Royal Medical Benevolent Fund Guild.—A produce market and fête will be held at the Royal Botanic Gardens, Regent's Park, on Wednesday, June 24th, from 2.30 to 9 P.M., in aid of the Guild. Promises of garden or dairy produce will be most gratefully received by Miss Stanham, the fête secretary, R.M.B.F.G. Office, 58, Great Marlborough-street, W. 1, who will send out official labels and directions for dispatch. If wet the fête will be held under cover at the gardens. Tickets (before 5 P.M. 2*s.*, after 5, 1*s.*, children 6*d.*) may be obtained beforehand from the secretary or any member of the committee.

Fellowship of Medicine and Post-Graduate Medical Association. — The second of the present series of lectures arranged by the Fellowship will be given by Sir Gerald Giffard on Wednesday, June 17th, at 5.30 P.M., on Some Madras Methods in the Teaching and Practice of Midwifery.—As the course arranged primarily for general practitioners by the London Temperance Hospital proved successful, it has been decided to hold another from June 22nd to July 4th.—The special course in Urology due to begin at St. Peter's Hospital in the middle of the month has been unavoidably postponed to June 29th to July 25th. Instruction will be given daily in the out-patient departments, and lectures dealing with the Diagnosis and Treatment of Urinary Diseases will be delivered by members of the staff.—From July 6th to 17th an intensive course in Cardiology will be held at the National Hospital for Diseases of the Heart. This course is strictly limited to an entry of 16, so that early application is desirable.—The Queen's Hospital, Hackney-road, will give a course in Diseases of Children from July 6th to 18th, and instruction will be available throughout the day in the various departments of the hospital.—From July 27th to August 15th the West End Hospital (out-patient department, 73, Welbeck-street) will hold a course dealing with the Diagnosis and Treatment of Nervous Diseases.—For full particulars and copies of the syllabus of the above courses, together with the programme of the Fellowship of Medicine, application should be addressed to the Secretary at 1, Wimpole-street, London, W. 1.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, June 15th.

Social Evening commemorating the birth of Charcot.

Special interest is given to this occasion as in addition to the address by Dr. Farquhar Buzzard on Charcot and the Centenary Celebration of his Birth, a collection of bibliography by Charcot and his pupils, made by Mr. Walter G. Spencer, will be exhibited.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

Thursday, June 18th.—7.45 P.M., Demonstration: 8.15 P.M., General Meeting. The new President, Dr. Andrew Balfour, C.B., C.M.G., will be inducted. The Chalmers Medal will be awarded to Prof. Warrington Yorke, who will read a paper on Further Observations on Malaria made during Treatment of General Paralysis, preceded by an announcement by Dr. G. C. Low on the use of a drug named " Smalarina " in the treatment of malaria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS.

Tuesday, June 16th.—5 P.M., Dr. S. A. K. Wilson: Disorders of Motility and of Muscle Tone with special reference to the Corpus Striatum. (Third Croonian Lecture.)

Thursday.—5 P.M., Dr. Wilson: Last Croonian Lecture.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, June 15th, to Saturday, June 20th.—West Lecture Hall, Royal Society of Medicine, 1, Wimpole-street. Lectures arranged by the Fellowship of Medicine and open to all members of the medical profession. Wed., June 17th, 5.30 P.M., Sir Gerald Giffard: Some Madras Methods in the Teaching and Practice of Midwifery.—Chelsea Hospital for Women, Arthur-street, S.W. Post-graduate Course in Gynæcology. Lectures and demonstrations daily. Operations, pathological demonstrations. (Second week.)—London School of Hygiene and Tropical Medicine, Endsleigh-gardens, N.W. Tuesday and Thursday at 2 P.M. Lecture-demonstration by Dr. P. Manson-Bahr and Dr. G. C. Low.—St. John's Hospital for Diseases of the Skin, Leicester-square. Daily demonstrations in the O.P. Department. Bi-weekly lectures by Dr. Fox and Dr. Whitfield.—City of London Hospital for Diseases of the Heart and Lungs, Victoria Park. Post-graduate Course in Chest, Heart, and Lungs. Lectures, clinical demonstrations, and laboratory demonstrations. (Second week.)—London Lock Hospital, Dean-street. Comprehensive Course. Daily out-patient instruction and lecture dealing with the diagnosis and treatment of V.D.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, June 15th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

Tuesday.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Wednesday.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—11 A.M., Dr. McDougal: Electrical Dept. 3 P.M., Dr. Pritchard: Medical Wards. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M., to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, June 16th.—4.30 P.M., Dr. F. Thomson: Demonstration of cases illustrating the Early Diagnosis of the Infectious Fevers (at the North-Eastern Hospital, St. Ann's-road, N.).

Friday.—4.30 P.M., Mr. J. Howell Evans: Hydrocele, Hæmatocele, and Pyocele.

Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.

Monday, June 15th.—Mr. R. Robison, D.Sc.: The Chemistry of the Calcification of Bone.

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-st., W.C.

Thursday, June 18th.—4 P.M., Dr. F. J. Poynton: Some Clinical Cases and their Lessons.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

Thursday, June 18th.—5 P.M., Mr. T. B. Davies: Ante-Partum Hæmorrhage.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: May–June, 1925.

Clinical Lectures and Demonstrations.

Monday, June 15th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Localising Signs of Cerebral Lesion: Dr. Riddoch.

Tuesday, June 16th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Compression Paraplegia: (1) Extramedullary: Dr. Grainger Stewart.

Thursday, June 18th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Cerebral Vascular Disease: Dr. Gordon Holmes.

Friday, June 19th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of Spinal Cord: Mr. Percy Sargent.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, June 15th.—12 noon, The Neuron: Dr. J. G. Greenfield.

A Course of Clinical Demonstrations will be given by Mr. H. J. Macbride, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 A.M. on Tuesdays and Fridays. The fee for this Course is £2 2s.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C. 2.

Tuesday, June 16th.—5 P.M., Dr. Fox: Seborrhœic Affections of the Skin.

Thursday.—5 P.M., Dr. Whitfield: Eczema.

THE JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

Monday, June 15th.—10.45 A.M., Dr. Orr: Cardiac Irregularities. 12 noon, Dr. Hynd: Clinical Examination of Urine. 4.30 P.M. (at the Bute Medical Buildings), Prof. Waterston: Structure and Development of the Heart.

Tuesday.—10.45 A.M., Dr. Maitland Ramsay: The Eye: Its Response to Effort. 12 noon, Dr. Orr: Demonstration of Polygraph. 4 P.M., Dr. Bryson: Capillaries.

Wednesday.—10.45 A.M., Dr. Rowand: Suspected Tuberculosis in Children. 12 noon (at the Bute Medical Buildings), Dr. Hynd: MacLean's Method of Estimating Blood-sugar. 4 P.M. (at the Bute Medical Buildings). Prof. Herring: The Action of Insulin.

Thursday.—10.45 A.M., Dr. Paton: A School Outbreak of Diphtheria. 12 noon, Dr. Hynd: Chemical Composition of the Blood. 4 P.M. (at the Royal Infirmary, Dundee), Prof. Patrick: Clinical Demonstration.

Friday.—10.45 A.M., Dr. Paton: Interpretation of Radiograms. 12 noon, Mr. Smith: Radiography of Duodenal Ulcer. 4 P.M., Case Reading.

Appointments.

Bulman, M. W. B., M.B. Lond., F.R.C.S. Eng., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Districts of the Aylsham, Downham Market, East Dereham, Fakenham, &c., County Courts (Circuit No. 32), in place of Sir Hamilton Ballance (resigned).

Ellman, Philip, M.R.C.S. Eng., L.R.C.P. Lond., Assistant Medical Superintendent to the West Middlesex Hospital, Isleworth, Middlesex.

Manchester Royal Infirmary: Bryce, A. G., M.D., F.R.C.S., D.P.H., Resident Surgical Officer; Sutherland, D. M., F.R.C.S. Eng., Surgical Registrar; Duguid, J. B., M.B. Aberd., Senior Pathological Registrar and Curator of the Royal Infirmary Museum; Twining, E. W., M.R.C.S., L.R.C.P. Lond., Senior Assistant Medical Officer in the X Ray Department.

Westminster Hospital: Davies, J., M.R.C.S., L.R.C.P. Lond., Davies, M., M.R.C.S., L.R.C.P. Lond., Davies, W. H., M.R.C.S., L.R.C.P. Lond., House Physicians; Dunlop, H. A., M.R.C.S., L.R.C.P. Lond., Coles, B. A., B.Sc. Wales, M.R.C.S., L.R.C.P. Lond., Wilson, J. G., M.B., B.S., M.R.C.S., L.R.C.P. Lond., D.P.H. Lond., House Surgeons; Isaacs, E. J., M.R.C.S., L.R.C.P. Lond., Resident Obstetric Assistant.

Certifying Surgeons under the Factory and Workshop Acts: Campbell, T., L.M.S.S.A., Sandy District of Bedford; Macmillan, C., M.B., Ch.B.Glasg., Tunbridge Wells.

Vacancies.

For further information refer to the advertisement columns.

Birkenhead and Wirral Children's Hospital.—H.S. £100.

Bradford Children's Hospital.—H.S. £100.

Brighton, Royal Sussex County Hospital.—Hon. S.

Cancer Hospital, Fulham-road, S.W.—H.S. at rate of £100.

Chichester, Graylingwell Mental Hospital.—Jun. M.O. £450.

City of London Mental Hospital, near Dartford, Kent.—Jun. M.O. £350.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Glamorgan County Council.—Dental S. £500.

Gordon Hospital, Vauxhall Bridge-road, S.W.—Res. H.S. at rate of £75.

Great Yarmouth Hospital.—H.S. at rate of £150.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P., H.S., Cas. M.O., and Cas. Surg. O. All at rate of £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. Also H.P. Each at rate of £50.

Hull Royal Infirmary.—Asst. H.S. at rate of £130.

Kirbymoorside, Yorkshire County Orthopædic Hospital.—H.S. £250.

Lanchester Rural District Council, &c.—M.O.H. £800.

London Jewish Hospital, Stepney Green, E.—Asst. S. to Ear, Nose, and Throat Dept. and Asst. S. to Gynæcological Dept.

London Lock Hospital, 91, Dean-street, W.—Clin. Asstships.

Manchester, Ancoats Hospital.—Res. S.O. £200. Also H.S. at rate of £100.

Manchester, St. Mary's Hospitals.—Two H.S.'s. Each at rate of £50.

Manchester University and Royal Infirmary.—Director of Lab. of Clin. Investigations. £600.

Margate, Royal Sea Bathing Hospital.—H.S. at rate of £200.

Newcastle-on-Tyne, Royal Victoria Infirmary.—Hon. Asst. S.

Northampton General Hospital.—Hon. S.

Preston and County of Lancaster Royal Infirmary.—Jun. H.S. £150.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Royal London Ophthalmic Hospital.—Refraction Asst. £100 for two mornings a week.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.

Surrey County Council.—Asst. M.O.'s in Pub. Health Dept. £600.

University College Hospital, Gower-street, W.C.—Asst. Radiologist at rate of £300.

West Bromwich and District Hospital.—Res. Asst. H.S. £180.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each at rate of £100.

Willesden General Hospital, Harlesden-road, N.W.—Vacancy on Hon. Med. Staff.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.

Births, Marriages, and Deaths.

BIRTHS.

Bulman.—On June 7th, at Baggallay-street, Hereford, the wife of Dr. J. R. Bulman, of a son.

Dupont.—On May 31st, at Bridge House, Frome, the wife of Dr. Dupont, of a daughter.

MARRIAGES.

Christie—Longwill.—On June 4th, at St. Columba's Church, Pont-street, London, Graham Wilson Christie, M.C., F.R.C.S.E., to Josephine Wright, daughter of Walter Longwill, Woodhey-road, Rock Ferry, Cheshire.

Fuller—Ingram.—On June 1st, quietly, at St. James's Church, Muswell Hill, Andrew Radburne Fuller, M.R.C.S., L.R.C.P., D.P.H., to Elizabeth Mary, younger daughter of Dr. and Mrs. P. R. Ingram, of Muswell Hill, N.

Rocyn Jones—Llewelyn.—On June 4th, at St. Paul's, Portman-square, W., Arthur Rocyn Jones, M.B., F.R.C.S., of 146, Harley-street, W., to Margaret, second daughter of the Rev. D. J. Llewelyn, formerly vicar of Beaufort, and Mrs. Llewelyn.

Stephen—Thorogood.—On June 4th, at St. Dunstan's Parish Church, Cheam, Surrey, Dr. William H. Stephen, M.B., C.M., of Westborough-road, Westcliff-on-Sea, to Ena Thorogood, daughter of the late A. R. Thorogood, of Pitsea.

Wiltshire—Tibbets.—On June 3rd, at St. Matthew's, Westminster, Harold Wiltshire, D.S.O., M.D., F.R.C.P., to Ellen, daughter of the late Edward Tibbets, M.D., of Bradford.

DEATHS.

Keen.—On June 3rd, after a short illness, Dr. Ernest Beresford Keen, T.D., Major, 13th London Regt. and R.A.M.C. (T.A.).

Lewis.—On June 8th, at Hamilton-terrace, St. John's Wood, N.W., after a very brief illness, Edward John Lewis, M.B., F.R.C.S., aged 65 years.

Sircom.—On June 1st, at a nursing home in Bristol, Edmund Ralph Sircom, M.R.C.S., L.R.C.P., of Romford-road, Stratford, Essex.

Sutherland.—On June 6th, at Pembridge-villas, W., Deputy-Surgeon-General Philip Warren Sutherland, I.M.S., in his 94th year.

Whitcombe.—On May 30th, at the Royal Berkshire Hospital, Reading, the result of a motor-cycle accident, Charles Henry Whitcombe, F.R.C.S.E., South Cerney, aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HEALTH EDUCATION IN CANADIAN SCHOOLS.

Sir William Hamer, medical officer of health and school medical officer for the County of London, took the chair at a meeting held in London on June 4th, when a large gathering of teachers, children's care workers, and school nurses listened to a lecture on this subject by Miss Jean E. Browne, president of the Canadian Nurses' Association and director of the Canadian Junior Red Cross. The speaker explained that health work in the Canadian schools began about 15 years ago, when a school medical service, based largely upon the English system, was set up. At first attention was directed to the correcting of physical defects and the limiting of the spread of communicable diseases. Later the general hygienic conditions of the school buildings received due consideration, while of recent years most important work has been done with regard to the health education of children and the formation in the children of health habits. Miss Browne described the school medical service as it exists in Toronto as an example of how the problem is tackled in the towns, and, pointing out that Canada is a great rural community, she described the school medical service in the province of Saskatchewan. The teaching of hygiene has undergone a great transformation in Canada within recent years. The more formal instruction has been supplemented by interesting games in which the children design health posters or act in health plays, while the older girls receive instruction in infant care in "little mothers" classes. Hygiene is now a compulsory subject in Canadian schools, from kindergarten to the end of the third year in the secondary schools. In the most junior classes there is no text-book nor formal teaching, but every effort is made to get certain habits firmly fixed in the minds of the youngest children. Later, when the children begin to ask why they need wash, or why they need fresh air and so forth, instruction in physiology is introduced and so on until the oldest children are led to study public health in many of its aspects, including such subjects as ventilation, clean milk, and housing. The training schools for teachers also give instruction in hygiene, so that the coming generation of school teachers will be well fitted to carry on the teaching of this subject in an interesting manner. To get the child's imagination and will to work requires something more than all this instruction, however, and this something more appears to have been found in the Junior Red Cross which is an organisation of the children themselves with world-wide ramifications. There is strong demand both by the school teachers and the public health authorities alike in Canada for the Junior Red Cross which appears to encourage in the children the desire for health and which, by its simple rules, is helping to build up a generation in which healthy habits will have been fixed since youngest childhood.

A NOVEL CERTIFICATE.

In the current issue of the *Military Surgeon* (May, 1925, p. 638) it is stated that, at the request of the Surgeon-General of the United States Army, a careful survey of the army general hospitals in the United States was carried out by the Director of Hospital Activities of the American College of Surgeons. All the five hospitals are reported as "fully approved," being far above minimum standards, and reaching maximum in most respects. They are recognised as having, in the words of the report, "proper organisation for general management, adequate facilities for diagnosis and treatment, efficient personnel, systematic procedure and technique, and a careful check-up and audit of the clinical work at all times." Such a report must be a comfort to mothers sending their sons into the American army.

RAT DESTRUCTION.

The enormous loss caused by rat infestation ought to arouse a more general effort to reduce their ravages. Mr. Mark Hovell, in a recently published book,[1] puts the loss in Great Britain alone at £1,000,000 per week and claims that this is certainly not an exaggerated estimate. He lays it down that each person should be held responsible for the rats on his premises and that if he does not have them killed, they must be destroyed at his expense. The advantages and disadvantages of all the different methods of rat extermination are discussed in detail. The opening chapter contains much of interest with regard to the habits of rats. Their extraordinary fecundity is, of course, one of the difficulties. The author shows that even with litters of moderate numbers a pair of rats may have very many descendants at the end of a year. Thus a pair of rats estimated to produce ten young ones in each litter and only six litters in the course of the year, at the end of the year will have 1130 descendants. Mr. James Rodwell, in his book, "The Rat," published many years ago, allowed only four litters in the year and eight young in each litter, and showed that even on these reduced figures a pair of rats could produce in three years 253,762 descendants. In an introduction to Mr. Hovell's book, Mr. S. L. Bensusan, who has been waging war on rats for 25 years, states that it is the most complete and reliable work on rat destruction yet to hand in any language. Certainly it should be studied by all whose duty it is to take part in the campaign against rats. The volume includes a scheme for the organised destruction of rats throughout Great Britain which merits the serious consideration of the Board of Agriculture.

CHESS AS A THERAPEUTIC AGENT.

It is a pleasure to read a book on chess which is so clear and well printed as the little volume entitled "The Elements of Chess," by Mr. J. Du Mont (London, G. Bell and Sons, Ltd., 1925, 7*s.* 6*d.*). Owing to the plentiful use of diagrams the reader is led without undue exertion from an elementary description of the game to a discussion on more advanced problems. If chess were boomed in the press in the same way as crossword puzzles it would surely gain and maintain a popularity unequalled even in an age of bridge and Mah-Jongg. For those many ills which are attributable to boredom a course of chess might suitably be prescribed, and this book could with advantage be recommended as part of the prescription.

POPULAR HANDBOOKS FOR WOMEN.

Ignorance is said to be mainly responsible for high infantile mortality-rates, so that the increasing number of popular or semi-popular books on mothercraft which have been appearing within recent times should have done something towards lowering the rate in this country. Authorities agree that the lower rate in certain parts of the country and the lowering of the rate for the nation as a whole are undoubtedly due to the spread of knowledge. Popular books on this subject, provided that they are free from excessive evidence of fads or crankiness, are therefore welcome and, even if they do no other good, a continuous insistence on the paramount importance of antenatal supervision and breast-feeding will eventually bear good fruit. Dr. Webb-Johnson's book [1] goes farther than this; he discusses brightly woman and her food, her sleep, her beauty, her dress, her home, and even her religion. Controversial subjects such as birth-control and twilight sleep are treated impartially, and sound advice is tendered with regard to marriage and the sex question.

Dr. Harry Roberts[2] does not travel so far afield and his book consists mostly of advice on marriage, pregnancy, and the management of children in health and disease. The language is simple, the advice reasoned, and here again certain controversial matters are dealt with.

Glasgow Victoria Infirmary.—This hospital of 260 beds is to be enlarged by a wing containing 120 beds, two operating theatres, and an addition to the nurses' home.

Donations and Bequests.—Miss Alice Woodhall, of Perry Bar, Birmingham, left by will £500 each to the Birmingham General Hospital; the Queen's Hospital, Birmingham; the Institution for the Blind, Edgbaston, the Home for Crippled Children, and the Hospital for Women, Birmingham.—Sir George Donaldson, Hove, left £1000 each to the London Hospital, the Sussex County Hospital, and the Royal Normal College of Music for the Blind.—The Liverpool Royal Infirmary has received £623, the Stanley Hospital £231, and the Liverpool Dispensary £40 from the proceeds of the Liverpool University students' "Rag" per the Liverpool Hospital Saturday Fund.—Mr. Robert Tatham, Lancaster, left £1000 to endow a bed at the Royal Lancaster Infirmary.—Mrs. Sarah Frances Underwood Fisher, Hove, who left £9587, directed that after payment of certain legacies one-half of the residue of her property be given to the Victoria Hospital, Swindon.—St. Mary's Hospital, Manchester, has received £1500 towards a legacy by the late Mr. James Parr.—Mr. Spencer Vere Hare, Bristol, left £500 to the Bristol General Hospital and £200 each to the Bristol Royal Infirmary, the Bristol Eye Hospital, and the Bristol Home for Crippled Children.

Some Anomalies
OF
LOCAL PUBLIC HEALTH ADMINISTRATION.

Being the Presidential Address to the Section of State Medicine and Municipal Hygiene of the Royal Institute of Public Health, on May 27th, 1925,

By Sir ARTHUR NEWSHOLME, K.C.B., M.D., F.R.C.P. Lond.,

LATE PRINCIPAL MEDICAL OFFICER, LOCAL GOVERNMENT BOARD.

The title of this Section indicates its special concern with problems of central and local public health government; and my remarks cannot be more usefully directed, especially at the present time, than in indicating some of the long overdue reforms in our administrative machinery which are called for by the advancing complexity of our problems and by the "obsolete, cumbersome, illogical, wasteful, and unjust" character of the machinery with which public health work has to be carried out. The words in inverted commas are the description given by Mr. Neville Chamberlain, the Minister of Health, on May 13th of our present system of rating and valuation; but they are equally applicable to our machinery of local government, reform of which we may now reasonably hope will follow the imminent reform of the basis of valuation for local rates and for Imperial taxes.

Central Health Administration.

The anomalies of central health administration have been greatly reduced by the Ministry of Health Act.* It is common knowledge, however, that anomalies of central administration remain which I am not concerned to consider in this address. Some of these anomalies are almost inherent in the unavoidable interlocking of different functions of government; and although I concur, for instance, in the urgent desire of Parliament, expressed most impressively in the passage of the Ministry of Health Bill through Parliament, and regret that this representative opinion was frustrated in the last stage of the Bill, I realise, as we all must, that both centrally and locally education authorities have an essential interest, not only in the hygiene of children, but also in their medical treatment, for the expression of which adequate opportunity must continue to be given. Similar remarks apply even more, so far as concerns the transfer of central control of the problems of factory hygiene and occupational disease to the Ministry of Health; and I content myself, as regards central organisation, with repeating the remark made in the volume already named:—

> "On balance one cannot doubt that there should eventually be a greater degree of central unification, while meanwhile friendly conferences are preventing friction, securing coöperation, and helping to obviate hiatuses in the health work common to several departments. This is an easy achievement when intensely parochial (intra-departmental) proclivities are kept in restraint."

But although the Ministry of Health does not deal centrally with all public health problems and is not concerned solely with these problems, its efficiency as a machine of public health government is hampered to the greatest extent by local causes of inefficiency in local government. This is no newly-realised fact. It has been painfully obvious to public health workers for a generation past, who have had with discouragement to ask, "How long? How long?" Hence, when, prior to the passing of the Ministry of Health Act, a pamphlet issued by the short-lived Ministry of Reconstruction made the following statements it was merely echoing this skilled knowledge.

> "Escape from the present impasse depends upon the general reform of the system of local administration . . . . The creation of an authority (with the express function of undertaking the care of the people's health as a whole) is the object of the Ministry of Health Bill—no light undertaking—still a means to an end rather than an end in itself . . . . The difficult question of the future structure of our local health organisation . . . . is the first and most bounden duty of the Minister (of Health) to take in hand upon his creation."

Reform of Local Government.

Looking at the problem from the standpoint of the different local authorities, it is stated in the same document:—

> "No proposal can be made at the present time for the extension or acquisition of powers by any one set of authorities without an outcry from some other set of authorities that their province is being touched upon."

The only way out is a root-and-branch reform of local government. Without this a Ministry of Health must continue relatively ineffective, and we may profitably devote a few minutes to an enumeration of some of the local anomalies which necessitate this root-and-branch reform of local government. The present occasion is particularly opportune in view of the fact that two Royal Commissions are now engaged in receiving evidence on the problems of local government and of health insurance administration. Although I have not had the opportunity of seeing the evidence given before either of these Commissions, its general trend must follow what many years of experience in administration has rendered familiar, and I propose briefly to set out three of the chief defects needing remedy and the general lines on which remedies for these three defects will need to be organised. This occasion is the more opportune in view of the recent second reading of the Ministry of Health's Rating and Valuation Bill. The passing of this Bill into law will represent the first step in the reforms which most of us desire; and its contents give hope that at least two of these reforms—namely, reduction in the number of local sanitary authorities and fusion of the work of boards of guardians with that of the larger public health authorities—will at last be secured.

The parish is an extremely interesting survival of English local history; and it had its value when each parish was almost entirely separate from other parishes. But modern life has completely changed governmental problems; and centralised supervision with some measure of control in essential matters but with liberally delegated powers to large authorities acting for wide areas has become necessary, in view of the consideration that schemes of water-supply and sewerage, of hospital and sanatorium provision, and of successful control over the problems of food-supply and of the spread of infections must hereafter be devised on a large and comprehensive scale if they are to secure the greatest degree of success with the greatest frugality of effort and expenditure.

Inefficiency of Small Sanitary Authorities.

The inefficiency of the smaller sanitary authorities has been frequently exposed. There are in England and Wales 1727 sanitary authorities, not including 82 county boroughs. The total of 1809 compares with 317 education authorities and 635 boards of guardians. No one has suggested that the efficiency of the work of either educational or relief authorities is lowered by the relatively large areas and population served by them; and every line of evidence points to the opposite conclusion.

Writing in my Annual Report to the Local Government Board (1907–8, p. viii.) of the small sanitary districts in the West Riding—which are among the most extreme illustrations of splitting off from larger administrative areas—I made remarks which with minor variations may be applied to the majority of smaller sanitary districts:—

> "Local self-government in such districts is both extravagant and inefficient. There is an unnecessary multiplication of officers, who cannot be paid sufficiently to devote them-

---

* The stages by which this point has been reached have been outlined by me in a small volume on the Ministry of Health and Public Health Administration (G. P. Putnam's Sons).

> selves without distraction to the public interests; on the part of the sanitary authorities of paltry districts like these, local and personal considerations too often outbalance the public interest, and the multiplication of small areas is a serious obstacle to an efficient and economical settlement of problems of water-supply and sewerage in which neighbouring districts are mutually concerned."

The following statement from my evidence before the Royal Commission on the Poor Laws (Appendix, vol. ix.) shows the allocation of population in Poor-law unions and in urban and rural sanitary districts. It may be taken as approximately applying at the present day.

> "Taking the country as a whole, the average population of sanitary areas is not much more than one-third that of unions. This is owing chiefly to the number of very small urban and rural sanitary districts. Of the total 660 rural districts and 1129 urban districts 8·5 per cent. of the former and 19·9 per cent. of the latter had a population under 3000, 18·4 per cent. of the former and 39·1 per cent. of the latter had a population under 5000, 52·4 per cent. of the former and 62·2 per cent. of the latter had a population under 10,000. On the contrary, only 12·7 per cent. of the Poor-law unions had a population under 10,000. These figures need to be partially qualified for the few districts which have combined to secure the services of a medical officer of health who devotes the whole or a large part of his time to the public service. Such combined authorities do not affect materially the general view that more than half of the sanitary authorities—happily, however, representing a much smaller proportion of the population of the country—consist of units of less than 10,000 population.
>
> "Experience has shown that, as area of administration is subdivided below certain minimum limits, so local personal interests predominate; and that, in accordance with this, a very large proportion of the smaller sanitary authorities are unworthy of their powers. Local considerations of expense and favouritism, and the insecurity of tenure of office of their sanitary officers, make efficient work an exception. A chief reason why sanitary progress has been impeded is furnished by the continued existence of these unsatisfactory small sanitary authorities. They do not as a rule obtain skilled advice, nor can they afford to obtain it when uncombined with other districts. Even when such advice is obtained, a small area of administration increases the risk of its neglect.
>
> "In considering, therefore, the work of sanitary authorities under any improved conditions, it is indispensable that the anomalously small authorities must be combined or redistributed into units of at least the same order of magnitude as that of the large majority of the parochial unions, so that each may have within the reasonable limits of its purse the minimum staff and equipment required for efficiency."

Since the above comments were made combination of areas for the work of the medical officer of health has occurred more frequently; but this does not secure the satisfactory administration which could be obtained by complete fusion of the sanitary authorities concerned. What is required is that the number of sanitary authorities should be reduced to one-third their present number, the smaller number, outside county boroughs, being organically related to public health administration on a county scale.

In the Rating and Valuation Bill the parish is abandoned as the unit of local administration, and in consequence the number of rating authorities will be reduced from 12,882 to 648; and this raises a hopeful expectation that ere long administrative sanitary units outside county boroughs will be reduced, as suggested above, to one-third of their present number, and that the areas for Poor-law administration will be made identical with those for public health administration. It is only by such means that an initial condition of satisfactory and economical public health administration can be fulfilled.

REFORM OF THE POOR-LAW.

This brings me to the second great reform in local administrative machinery, the accomplishment of which is already terribly belated. When separate school boards ceased to exist, and local education authorities became an integral part of the larger public health authorities, an important step was taken in the direction of securing for (in most instances) suitably large local areas that all the functions of local government should be concentrated in what is essentially a Parliament for local government, subdivided into committees for executive convenience, but the action of all these committees subject to approval by the one local authority. No sound administrative reason can be advanced for the continued exclusion of boards of guardians from this principle.

Every branch of public administration benefits by contact and exchange of views and experience with every other branch, and this is particularly true of the problems of destitution, which in very high measure imply the need for reducing the duration and gravity of disabling illness by efficient treatment and still more by the prevention of every form of preventable disease. It would take too long to set out the historic and the administrative reasons which necessitate a readjustment of local destitution work. Foremost among these, as you know, is the fact, that the work of Poor-law guardians has ceased to be chiefly the relief of the able-bodied destitute; and that now its chief work is on behalf of sick persons and of destitute women and children. In fact, destitution, in the official sense of the word, is largely a function of age, the number of persons in receipt of parochial relief at ages 0–5 being 1 in 73 of the total population at these ages, 1 in 303 at ages 15–25, 1 in 151 at ages 25–35, but increasing to 1 in 6 at ages 65–75, and 1 in 3 or 4 at ages 75 and upwards. (The figures relate to a census of paupers in England and Wales on a given day in 1906.) The age distribution of pauperism illustrates the importance of old-age pensions and of the additional provision for widows and for persons over 65 about to be made; and it gives an additional reason for redistribution of the work of relief of destitution according to its causation and character.

The needed data for reform and the directions which reform should take are adequately set out in the reports of the Royal Commission on the Poor-law issued over a dozen years ago after an inquiry lasting four years; and the more recent recommendations of the Maclean Committee issued in 1917 give the agreed conclusions of those who previously had written the partially discrepant Majority and Minority Reports of the earlier Royal Commission. The main recommendation of the Royal Commission and of the more recent Committee alike is that the boards of guardians should be abolished as separately elected bodies, and that the administrative areas should be those of counties and county boroughs, which number 144. Whether this number shall be strictly followed, or whether the areas of the new rateable districts which are proposed shall be followed is a question for detailed consideration. But if, outside county boroughs, county areas are subdivided it is most desirable that the county council should be the chief authority in the county area and that for administration both in respect of public health and destitution all local authorities should be functionally affiliated to the county council.

This does not complete the toll of desirable liaisons and affiliations. Experience in public health administration and in the provision of institutional accommodation for the mentally and bodily sick has shown that further amalgamation is needed for special purposes. Water schemes are often unnecessarily extravagant, which do not include both county and county borough populations; the same remark applies to many sewerage problems; to the difficulties of river pollution; and often even more to institutional provision for the insane, for the feeble-minded, for surgical tuberculosis, for maternity cases, for small-pox, and so on.

METHOD OF SECURING COMBINED ACTION.

To secure such combined action as has been suggested two courses, at least, are practicable; action through a combined committee, or one authority acting for the other on agreed terms, subject, in the event of differences, to the final arbitration of the Ministry of Health. It is of the essence of such combinations for special purposes that they should not be terminable, except by mutual consent, and with the sanction of the Ministry of Health.

When we look at the problems of our multiform local administrations and of occupational disputes we cannot boast. Let me instance a recent experience in a town not very remote from our place of meeting. This town, like so many others, had to seek for part of its water-supply outside its own borough boundaries, in this instance from deep wells with long adits bored in the chalk hills. These adits were in proximity to scattered houses and farmsteads in rural districts, whose drainage went partially into soaking cesspools. The town in question had for many years made monthly bacteriological examination of each of its five sources of water-supply, and had through its officials made inspections and inquiries, so far as was practicable, of the sanitary circumstances of all dwellings within the range of the gathering-grounds of its water-supply. In doing so there had been ascertained sources of possible contamination which it was necessary to control, and in a recent year the town council applied successfully to Parliament for power to make by-laws respecting premises outside its administration but within two miles of its pumping-stations, the enforcement of which would protect the water adits from sewage percolation. The by-laws so far as they are enforced will be expensive to the town council, and cost nothing to outside authorities or owners of property, inasmuch as the town council will be called upon to pay any expense, which would not have been necessary had the by-laws not been in force—e.g., in constructing and emptying cesspools and in laying sewers uncalled for except for protection of the borough's water-supplies.

But although this was so, the councils of two administrative counties, and of five rural or urban district councils lodged petitions against this most expensive legislation—expensive not to these councils, but to the borough council which was striving for ideal safety of its water-supply. The absurdity of such action is further illustrated by the fact that the borough supplied some of the petitioning authorities with their water. Such waste of public money and such petty refusal to look at a sanitary problem from the standpoint of the persons chiefly concerned ought in this day to be impossible. True, the borough council might by chlorination of the whole of its water-supply have materially reduced the risk implied in the continued license of the inhabitants of surrounding districts to empty their cesspools into the porous chalk of the gathering-ground of the public supply of water. Such chlorination is, of course, important wherever any work of extension of wells or of adits is in progress; but to require that possible contamination of the gathering-ground shall continue, and the effects of this nastiness shall subsequently be counteracted by chemical disinfection—even though this sometimes is necessary, when safety cannot otherwise be reached—is contrary to the first principles of preventive medicine.

The above instance of lack of coöperation, of a failure of the spirit of "team-work" on which human progress so largely depends, doubtless could be matched in the experience of others.

Hospital Beds.

So far I have emphasised the need for larger units of sanitary administration in many areas, and for making the important advance towards a local Parliament for all local purposes, by transferring the work of boards of guardians to the 144 or more larger authorities. Before passing on from this last point let me bear my testimony to the value of much of the work of the guardians for the sick poor, and my expression of belief that in the prospective new conditions the guardians will be able to continue their work on a larger scale, with specialised medical institutions, in which the differences between parochial and public health patients will have disappeared, and in which the quality of their work can be greatly increased.

According to an official hospital return made in 1915, the number of hospital beds provided by different authorities in England and Wales was over 300,000, of which 15 per cent. were in voluntary hospitals, and the remaining 85 per cent. were supplied by public health and Poor-law authorities—viz., 12 per cent. of the total in hospitals for fever, small-pox, and tuberculosis, 39 per cent. in asylums for the insane and institutions for the feeble-minded, and 34 per cent. in infirmaries and workhouses. The Poor-law infirmaries have been in largest measure the refuge of patients suffering from chronic disabling and incurable illness and have thus supplied a great public necessity. I have elsewhere given reasons for the conclusion that the protracted treatment of bedridden and advanced cases of open tuberculosis in these institutions has been an extremely important factor in diminishing massive infection by tubercle bacilli, and thus in bringing about that remarkable reduction in our national death-rate from tuberculosis which is proceeding with undiminished rapidity.

But at present we have the unfortunate picture of unoccupied wards and beds in Poor-law infirmaries, and especially unoccupied lying-in wards and beds, while voluntary hospitals find it difficult to provide the accommodation sought for, and while public health authorities are providing lying-in beds and beds for advanced consumptives in special institutions, apart from the Poor-law infirmaries. For this and for many other reasons there is urgent need for the assembly of all official hospital accommodation under a single local authority, and for a closer association between official and voluntary hospital accommodation.

The consideration of the medical problems of the Poor-law and the implied conclusion that all forms of treatment of disease must be related to a national policy or prevention of disease, both undertaken by the same authority, naturally leads to a consideration of the machinery of the national system of insurance against sickness; and it is in this connexion that there emerges the third great line of advance in public health administration, which is called for in the public interest.

National Health Insurance.

I am not concerned to discuss here the defects in the National Health Insurance system except in so far as they relate to local administrative machinery though in passing I may express a regret that the system was introduced prior to the reform of the Poor-law which in 1908 had already been recommended after four years' investigation by a Royal Commission. Had the order of events been different the medical and the administrative problems of health insurance would have been less complicated, its practice more economical and efficient, and not, as at present, without the residential provision for patients which, inter alia, is still lacking to make the medical treatment of insured persons satisfactory.

The policy of insurance against the chief risks of life is reasonable and wise; and the community is so vitally interested in the satisfactory medical treatment and maintenance of its sick as to render it a wise precaution to contribute a large share of the expenditure needed to secure this. But as representatives of public health authorities you will scarcely need to be reminded that insurance is not prevention. Insurance against sickness, in fact, assumes the necessary continuance of sickness, and per se makes no provision for the reduction of sickness.

But although insurance is not an alternative to prevention, it may, when it becomes satisfactorily organised, greatly facilitate and stimulate preventive measures. The analogy of fire insurance and of insurance against motor accidents indicates one line of possible progress, additional benefits being secured by reduction of claims for sickness. The great stumbling block in the adoption of prevention as a chief plank in the policy of insurance against sickness is the fact that while medical benefit is administered by local insurance committees who alone arrange with medical practitioners for ordinary domiciliary medical attention, monetary benefits—and unhappily there is included in these the maternity benefit—are administered by the various friendly societies and limited liability companies. These are not "territorialised"—if one may coin a word—and consequently local experiences cannot be compared, with a view to obtaining accurate information of excessive sickness. Nor are they "industrialised," thus enabling occupational sickness to be studied. On the other hand, the insurance committees act for county and county borough areas; and they have no direct relation geographically and but little relation functionally to the numerous societies or companies who compete within their area for the patronage of insured persons. Equal weekly payments are made by all insured persons for very unequal risks; and though this can be defended, it is scarcely defensible that in societies in which the need for extra benefits is greatest the surplus society funds available for this purpose are at their lowest. Even if it be not immediately practicable to territorialise the administration of sickness insurance, there is urgent need for treating in this way the surplus funds of all insurance societies and companies, and for applying these surplus funds to urgent medical needs. Among these in the order of importance and urgency may be mentioned the provision of hospital beds for all insured persons who can be more satisfactorily treated in hospital than at home, consultant facilities in all cases of dubious diagnosis, the provision of a national dental service, and the subsidisation of our county and district nurses to an extent which would make them available for every case of sickness in which the "panel" doctor asks for them. Perhaps before any of these should have been put the provision of laboratory facilities for diagnosis and treatment. In the Budget of 1914 a large Treasury grant was promised for this purpose, and though the Great War prevented the adoption of this scheme—which would have included physical and chemical as well as pathological laboratory facilities not merely for insured but for all patients—we may hope that this important lack in the scientific treatment of disease will ere long be met.

The need for the application of many of the medical reforms suggested above to others than insured persons need scarcely be stressed; and in this connexion much interest attaches to schemes of medical services which in recent years have been adumbrated, and to the admirable pioneer effort, made on the initiation of Dr. Middleton Martin in Gloucestershire, to provide a correlated system of medical help for the community.

But my main intention in this address is to limit my remarks to administrative machinery. In regard to insurance against sickness, I have already indicated that the unequal distribution of surplus funds in different societies—derived like their total funds to the extent of about 60 per cent. from contributions of the State and of employers, and of only about 40 per cent. from the insured persons themselves—under present society and company administration is an effective block to a more efficient service, and especially to a uniformly efficient service. This is especially so for the maternity benefit, and I enter a special plea in regard to this share of the present sectionalised monetary administration. What possibilities of increased good, of diminished maternal mortality and invalidism, and of lowering of the toll on infant life, especially during the first month after birth, would be developed were this fund administered by county and county borough councils as part of their maternity and child welfare schemes.

The residuum of insurance administration left nominally in the hands of the local insurance committee relates to the local work of panel doctors, but owing to the necessary centralisation of this work by means of the Ministry of Health's regulations they have little to do; and they can only be revitalised by the reconstitution of these committees as integral parts of county councils and county borough councils. Whether when thus reconstituted they should function separately from the other committees of these bodies which are dealing with medical services is a subject for detailed consideration.

LINES OF REFORM.

It is evident, then, that three great lines of reform of local administrative machinery are required. I might have enlarged the list by emphasising that the larger local authorities should take a larger share than at present in industrial hygiene by indicating the need for merging the certifying factory surgeon's work in that of the local public health service, for a closer identification of the local school medical service with the public health service, where this is not already secured; and other improvements in local machinery will doubtless occur to you. But the three problems I have outlined overshadow all others; and when we have larger public health authorities, which embrace in their work the medical care of insured persons and of the destitute, the public health service will have travelled far towards that efficiency and completeness of public health administration which alone is compatible with the economy of public health and life, as contrasted with the short-sighted parsimony which refuses to pay the price of health.

Oliver-Sharpey Lectures

ON THE

INTERPRETATION OF THE ELECTROMYOGRAM.

Delivered before the Royal College of Physicians of London on May 5th, 1925,

BY E. D. ADRIAN, M.D., F.R.C.P., F.R.S.,
FELLOW AND LECTURER OF TRINITY COLLEGE, CAMBRIDGE.

LECTURE II.*

BEFORE we can say how far the recording of the electromyogram will be of real value in neurology we must answer the question which was left undecided in the previous lecture. The oscillating action currents show that during a voluntary contraction the muscle is activated from 50–250 times a second, and the point we have to settle is whether the nerve impulses recur at the same or at a much higher frequency. Given a picture of the fluctuations of current in the muscle, how are we to discover whether this picture corresponds more or less with what is happening in the motor nerve-fibres and in the motor centres of the cord? The most obvious way would be to make simultaneous records of the action currents in the motor nerve and the muscle during a reflex contraction and to see if they agree in frequency. Unfortunately, technical difficulties have stood in the way except in one or two instances. The difficulty lies in the recording of action currents from the motor nerve. When the muscle contracts reflexly in response to a single induction shock to an afferent nerve, it is possible to detect the action current in the motor nerve, though it is a great deal smaller than that produced by stimulating the motor nerve itself. Forbes[1] has shown that this small size is probably due to the fact that in the reflex the motor fibres are not all active at exactly the same moment; also there are many fibres in the nerve-trunk which do not become active at all in the reflex. The lack of synchronisation is probably a great deal worse in the usual reflex to such a stimulus as pinching the skin, and at any rate attempts to record the succession of reflex action currents in the nerve have usually failed. What evidence we have is to some extent conflicting. Veszi[2] found that during the convulsions produced by strychnine in the spinal frog, the motor nerves showed small action current oscillations at the same frequency as those in the muscle (about 40 a second). On the other hand, Athanasiu[3] describes oscillations of a much higher frequency (500–1000 per second) in the sciatic nerve of a dog during movements of progression. Forbes and Cattell[4] find nothing corresponding to this in the popliteal nerve during decerebrate rigidity although triode valve amplification was used.

---

* Lecture I. appeared in THE LANCET last week.

Action Currents in the Phrenic Nerve.

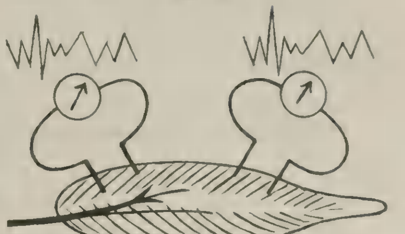
In one case, however, the evidence seems to be quite conclusive, and this is the case of the action currents in the phrenic nerve during the movements of breathing. The phrenic is an ideal nerve for this kind of investigation, as it is long, unbranched, and contains no fibres except those to and from the diaphragm. Dittler and Garten[5] found that during the movement of inspiration it was just possible to record a series of very small action currents in the phrenic with a frequency of the order of 70 a second, which corresponds closely with the frequency of the action currents in the muscle. This result was amply confirmed by Gasser and Newcomer[6] in 1921 with the aid of a valve amplifying system in conjunction with the string galvanometer. This gave an amplification of about 500 and showed the action currents in the phrenic as a series of large waves occurring in groups of 100–150 at the rate of 70–100 a second. The frequency of the responses in the phrenic corresponded very closely indeed with the frequency of the responses in the diaphragm muscle, simultaneous records of the two showing the same irregularities.

This work leaves no room for doubt that the movement of the diaphragm is brought about by a discharge of impulses at the rate of not more than 70–100 a second from the cord, and that each volley of impulses in the nerve produces a corresponding wave in the action current record of the muscle. It is noteworthy that the impulses in the different nerve-fibres must have been more or less in phase with one another to have given such definite waves as those found by Gasser and Newcomer, though the volleys of impulses are not discharged at perfectly regular intervals. No doubt the same is true of the discharge of impulses from the cord during strychnine convulsions where Veszi found definite waves in the nerve-trunk.

Action Currents from Different Parts of a Muscle.

In the case of the phrenic nerve and the diaphragm, therefore, the electromyogram gives us a valuable picture of the activity of the motor centre, since the successive impulses in the nerve-fibre do not recur too rapidly for the muscle-fibre to follow. It is arguable, of course, that the semi-automatic innervation of the diaphragm may differ from that of a skeletal muscle, the frequency of the nerve impulses being much higher for a voluntary movement than for one like breathing. There are, however, certain less direct lines of evidence for the view that in skeletal muscle, too, the frequency of the nerve impulses is no greater than that of the waves in the electromyogram. The most important is that brought forward by Bass and Trendelenburg.[7] Using two pairs of needle electrodes they led off the action currents from two distinct regions in a muscle and recorded them simultaneously with two galvanometers. They found that the waves showed a very close correspondence in the two records as long as the distance between the two pairs of electrodes did not exceed about 5–6 cm. The electrodes were so arranged that a current in the one circuit would not affect the other and that the two pairs would be in connexion with different muscle-fibres. The agreement of the waves recorded by the two strings certainly suggests that each corresponds to a volley of impulses from the motor centre (Fig. 1). It is not surprising that there is no longer an agreement when the distance between the two pairs of leads is increased to more than 5 cm. It means no more than that the whole of the motor neurones to a large muscle do not always act in complete unison. If the irregular response of the muscle had been produced by a much more rapid series (regular or irregular) of impulses in the nerve-fibres it seems unlikely that two different groups of muscle-fibres would show the same irregularities, but the experiment is not altogether conclusive, for sometimes an extremely rapid regular series of stimuli to a motor nerve (800 a second) will produce large irregular action currents in the muscle. From the size and arrangement of these it is difficult to avoid the belief that most of the muscle-fibres are responding synchronously, though why they should do so is not very clear. The chance of this occurring might be greater if the impulses in the nerve-fibres were irregularly spaced, and the irregularity of the muscle response might then be determined by this spacing without necessarily bearing much resemblance to it.

Fig. 1.

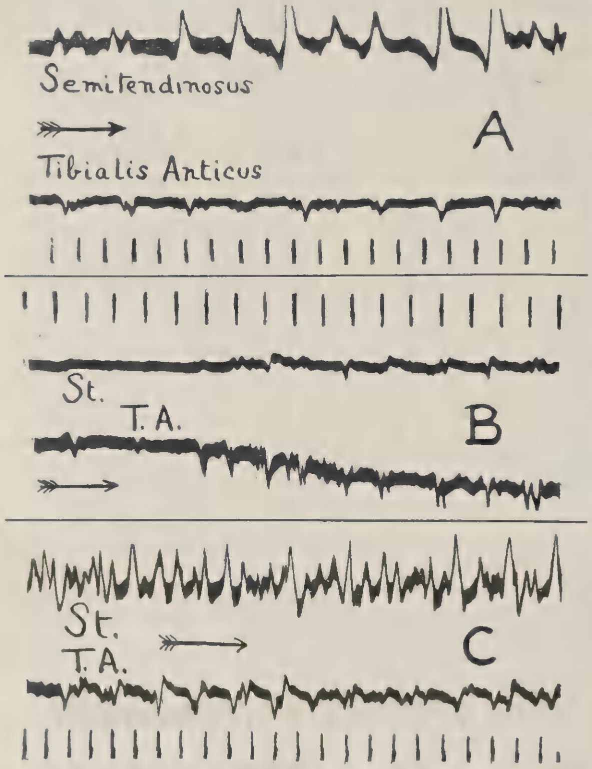


Bass and Trendelenburg made the further interesting experiment of comparing the action currents in the right and left temporal muscles. Although these act together as a rule, they found that there was no correspondence in the two electromyograms. Taken in conjunction with their evidence of correspondence in two regions of one muscle this can only mean that the volleys of impulses from the right and left motor nuclei are not identical. In the case of the diaphragm, on the other hand, Gasser and Newcomer found corresponding waves in the two phrenic nerves, so that here both motor centres must act in unison. I have occasionally found a close correspondence in the action currents of two synergic muscles contracting together in a reflex. Fig. 2, A and B, shows two records of this kind taken from the semi-tendinosus and tibialis anticus of a spinal (decapitated) cat during the flexion reflex. The reflex was produced by pinching the foot, and the movement was jerky and intermittent. The electromyogram consists of discrete waves or small groups of waves at a low frequency with definite pauses between them, and the waves in the two muscles agree fairly closely. The agreement comes to an end as soon as the contraction becomes continuous (Fig. 2, C). The same kind of agreement is found in the groups of electric responses which occur during a strychnine convulsion in the two muscles. Evidently the spinal centres must discharge nearly simultaneously to produce these identical waves, but it is quite possible that the discharge consists of a very rapid series of impulses in each nerve-fibre, the muscle responding only once or twice to each series.

Evidence for High Frequency in Nerve.

So far the evidence has been in favour of the view that each wave in the electromyogram can be taken to represent a volley of impulses from some of the spinal motor neurones. In the one case of the phrenic the evidence is conclusive. There are two observations which seem to favour the opposite view—that the nerve impulses recur much faster than the waves in the electromyogram. One is the undoubted fact, shown by Forbes and Rappleye,[8] that cooling the muscle decreases the frequency of the waves in the electromyogram. As the cooling has not affected the central nervous system it appears that the frequency of the electromyogram depends on the state of the muscle and is not determined entirely by the rate of spinal discharge. This conclusion would be inevitable if the cooling could be strictly confined to the effector organ, the muscle, but an element of doubt comes from the fact that the sense organs and sensory nerve-fibres in the muscle are cooled too, so that both ends of the proprioceptor arc have been interfered with. Dusser de Barenne[9] finds that the frequency of the electromyogram is reduced by injecting novocaine in dose sufficient to interfere with muscle sensation but not with voluntary power, and the reduction in the cooled muscle may also depend on a partial failure of the proprioceptor supply. In the absence of exact measurements of the temperature within the muscle and of the sensibility of the muscles and joints, it is difficult to say whether the cooled muscle really behaves as it does because it is ataxic, but Miss Cooper and I[10] have investigated the parallel case of the reflex movements of spinal animals, and we found that a very considerable temperature reduction was necessary before there was any change in the electromyogram frequency.

FIG. 2.



A and B, Simultaneous records from the semitendinosus and tibialis anticus during the flexion reflex in a spinal cat. Reflex evoked by pinching the foot. The records show synchronous waves in the two muscles. Time marker records 1/50 sec. intervals. C, Reflex fully developed. The waves do not now agree.

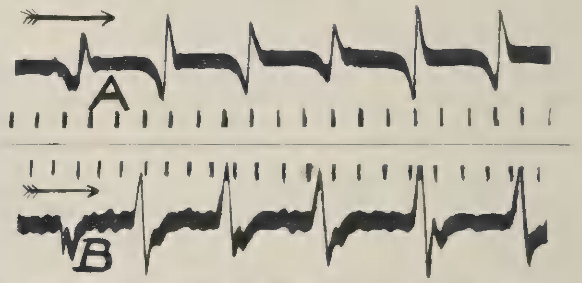
The temperature effect is not conclusive therefore. The other line of evidence is that brought forward by Athanasiu, and it depends on the observation of very rapid oscillations in the records taken from motor nerve-trunks during reflex movements. This again is not altogether conclusive, for Athanasiu finds much the same small, rapid oscillations in the record from the muscle. He regards these as due to the intramuscular nerve-trunks, but Forbes has pointed out that this interpretation is quite untenable, since the action currents of the intramuscular nerves would be far too small to affect a galvanometer leading off from the muscle.

It is to be hoped that the whole question may be cleared up before long by an extension of what we may call the Gasser and Newcomer experiment to other nerves than the phrenic and other movements than those of breathing. Meanwhile, however, we have a prima facie case for supposing that each of the larger waves in the electromyogram is produced by a volley of impulses from the motor centre in the cord, and that the appearance of a fairly regular succession of large waves (as in a maximal voluntary contraction) implies a fairly regular succession of volleys, the motor centre "beating" as a whole with only a few neurones out of phase with the majority.

EFFECTS OF RHYTHMIC STIMULATION.

A rhythmic discharge of this kind might have two possible explanations. It might depend on the natural period of the spinal motor neurones themselves, or it might be due to a rhythmic sequence of impulses arriving at the spinal motor centre from some other part of the nervous system. Now Sherrington has pointed out that the final common path of several reflex arcs should be aperiodic, since it must take part in many different types of response. But in this sense "aperiodic" means only that the final common path should have no period of its own measured in seconds or minutes; periodicities as short as 1/50 or 1/100 second are quite another matter and the argument does not profess to take them into account. The trend of recent work, starting with that of Beritoff, has been to show that the spinal motor neurones are not limited to one definite frequency. They can certainly be made to discharge at many different frequencies up to and over 100 a second if a rhythmic sequence of impulses reaches them.

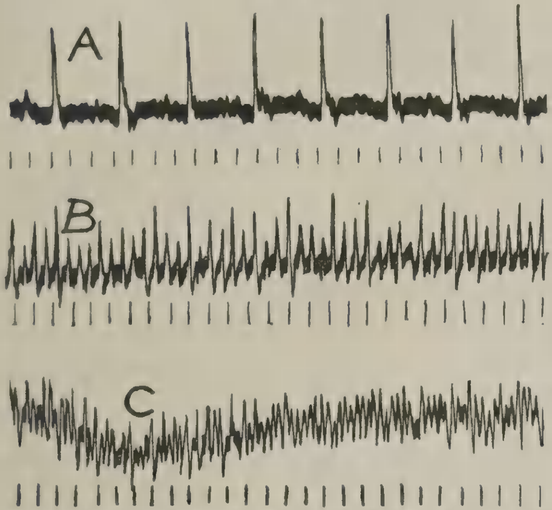
FIG. 3.



Flexion reflex in spinal cat evoked by rhythmic stimuli (induction shocks to the popliteal nerve). Response of tibialis anticus. A. Weak stimuli, about 13 a sec.; response consists of primary waves only. B. Stronger stimuli; secondary waves as well as primary.

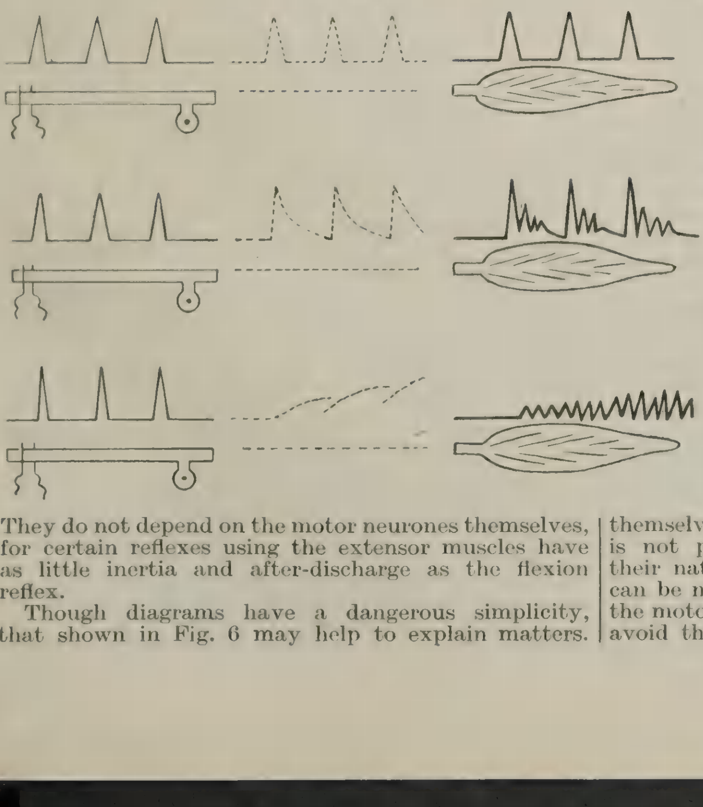
If the flexion reflex is produced in a spinal cat by pinching the foot, the electromyogram shows the usual irregular oscillations at the usual frequency, but if instead of a "natural" stimulus such as pinching we use an electric shock repeated regularly, then the response bears very clear indications of the frequency of the stimuli. The relation of the response frequency to the stimulus frequency in different reflexes and in different conditions of the central nervous system has been very fully investigated by Liddell and Sherrington[11] using the mechanical response of the muscle recorded with a high-period isometric lever, and Miss Cooper and I[12] have found much the same results with the electric response. These experiments show that in certain reflexes, of which the flexion reflex in the spinal animal is a typical example, the response is very closely related to the stimulus, almost as closely as it is in a muscle and nerve preparation. The contraction attains its maximum almost at once and does not persist for more than a few seconds after the stimulus has ceased. The plateau of the contraction shows well-marked notches corresponding in frequency to that of the stimuli, and the electric response consists of a series of large action currents at the same frequency. The agreement only fails when the stimulus frequency is raised to 250–300 a second. If the stimuli are weak and the response poor (as in an animal suffering from loss of blood), the electromyogram consists of nothing but the large "primary" waves corresponding with the stimuli. With stronger stimuli, or in more active preparations, the intervals between them may be filled in with a number of small "secondary" waves (Figs. 3 and 4). If, instead of flexion, we record the crossed extension reflex, the time-relations of the response are quite different. Liddell and Sherrington find that the contraction rises slowly to a plateau and may remain long after the stimulus has ceased. The electric response may show primary waves when the stimulus frequency is low, but there is often no sign of them, the record consisting of a rapid, irregular succession of small waves (Fig. 5). Sherrington classifies a reflex of this kind as of the "Recruitment" type in view of the gradual, instead of abrupt, increase in the strength of contraction, and he points out that the response shows what may be well compared with mechanical *inertia* in its slow development and *momentum* in its tendency to outlast the stimulus. The different types of response preserve their character in spite of the division of the sensory fibres which arise in the muscles themselves, so that the differences evidently depend on the central connexions of the various arcs. They do not depend on the motor neurones themselves, for certain reflexes using the extensor muscles have as little inertia and after-discharge as the flexion reflex.

FIG. 4.



Flexion reflex in spinal cat with rhythmic stimulation. More excitable preparation than that in Fig. 3. Frequency of stimuli in A 17 a sec., in B 90 a sec., in C 160 a sec. The response shows primary waves at the same frequency.

FIG. 6.



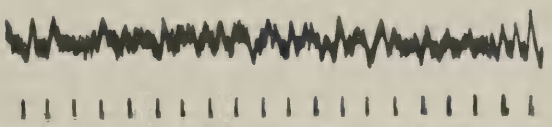
Though diagrams have a dangerous simplicity, that shown in Fig. 6 may help to explain matters. This diagram represents each volley of afferent impulses as calling up an unspecified "central process," which in its turn determines the response of the motor neurones. According as the time-relations of the central process are abrupt or gradual we shall have a reflex of Sherrington's "*type d'emblée*" or of the recruitment type. But even when it is of the latter type, where the response does not follow the rhythm of the stimulus, there is still no indication of a definite periodicity in the central process or in the motor neurones, for the small waves have no definite frequency.

So far, then, we have no evidence of a natural period in the motor neurones. But in the last analysis it is clear that the motor neurone does have a period of its own, for the nerve-fibre enters into the usual refractory state after an impulse has passed down it, and this limits the maximum frequency of response in the nerve to about 1000 a second. There is some evidence that the refractory period of the central part of a reflex arc may be longer than this, nearer 1/300 second, for it seems to be impossible to get rhythmic discharges from the cord at a higher frequency than this.[13] But the evidence for this is, perhaps, not conclusive. In any case these very short time intervals are a long way from the 50 a second rhythm of the voluntary contraction, and yet the rhythm in the latter may be almost as definite as the rhythm in a reflex produced by stimuli at 50 a second to the afferent nerve.

NATURAL FREQUENCY OF MOTOR NEURONES.

One possibility which must be considered is that the nerve cells have a natural tendency to discharge at 50 a second, and yet are able to discharge much more rapidly when afferent impulses reach them at a higher frequency. The heart may be taken as a parallel case, for here the frequency of the normal beat is a good deal less than the maximum frequency at which the heart can be driven. The strongest argument in support of this view of an intrinsic frequency in the motor neurones comes from some recent experiments, as yet unpublished, which Dr. Dusser de Barenne has kindly allowed me to quote. Working with Dr. Brevée, he has investigated the effect of local application of novocaine to the exposed cord isolated from the brain. If a reflex movement is produced by touching the dorsum of the exposed cord, before the use of novocaine the usual very irregular electromyogram is recorded. Novocaine is now applied to the dorsum of the cord, so that, as it penetrates, more and more of the nervous structures will be thrown out of action. The result is that the electromyogram becomes progressively more and more regular, and finally, just before the movements cease to be produced by touching the cord, the response shows an extremely regular rhythm of about 50 a second. At this stage we may imagine that most or all of the afferent structures are out of action and the stimulus takes effect directly on the anterior horn cells (which succumb themselves very soon afterwards). The stimulus is not periodic, but the motor cells respond with their natural rhythm of 50 a second. Since there can be no question here of a rhythmic excitation of the motor cells by afferent impulses, it is difficult to avoid the conclusion that the period is that of the

FIG. 5.



Crossed extension reflex. Decerebrate cat. Response of quadriceps extensor. Stimulation at 30 a sec., but no evidence of waves at this frequency in the record.

cells themselves and that they are so connected that they discharge in unison.

Effect of Afferent Impulses Arising in the Muscles.

There is, however, another very important group of experiments which shows that periodic afferent impulses may have a considerable effect on the frequency of the voluntary electromyogram, just as they do in the flexion reflex. These experiments have been carried out by Hoffmann[14] and Preisendorfer, and they are concerned with the relation of the tendon reflexes (Eigenreflexe) to the rhythm of the contraction. If the proprioceptors of a muscle are stimulated by making the muscle contract suddenly by an electrical stimulus, or by a sudden mechanical jerk, there is usually the answering reflex twitch of which the familiar tendon jerk is the typical example. If the stimulus is rapidly repeated, the reflex effect is also repeated at the same frequency (up to 100 a second or more), but in an uncontracted muscle the reflexes may be extremely small or absent altogether. If, now, a voluntary contraction of the muscle is produced during such repeated stimulation of the sensory endings in the muscle, the electromyogram does not show the usual irregularity. Instead it consists of a series of large waves having the frequency of the stimuli with very small irregular waves between them. In fact, the record is now little more than a series of greatly augmented proprioceptor reflexes. The cortical effect has been to make the anterior horn cells respond much more readily to the periodic afferent impulses which formerly produced only a very slight response.

It seems, then, that the cortical influence by itself can have very little tendency to determine any particular frequency of discharge from the motor neurones, for these are free to pick up whatever frequency happens to be reaching them from the proprioceptor paths. It is possible that a regular frequency of discharge might arise whenever the natural period of mechanical vibration of the muscle happened to coincide with the latent period of the reflex. The contraction would then consist of a series of twitches, each one stimulating the proprioceptor endings and so evoking the next—the whole process being something like an ankle clonus on a much finer scale. The rhythm would then be determined by the time taken between the stimulus and the reflex response, and it is true that in several cases this is of the order of 1/50 second. But in some (particularly those from the arm muscles) it is a good deal shorter, and Hoffmann very wisely refuses to theorise as to the precise relation of the proprioceptor reflexes to the normal voluntary contraction.

Effect of Other Afferent Impulses.

It might seem likely that other afferent impulses besides those arising in the muscles might have an effect on the frequency of discharge from the motor cells. As we have seen, in the flexion reflex of the spinal cat a rhythmic stimulus to the skin or to any of the sensory nerve trunks leads to a response in which the stimulus frequency is clearly marked, and possibly the same result might be given in a baby or in an adult with complete division of the cord. In the normal adult, however, a painful stimulus to the foot does not produce a flexion reflex, and in the movements which do occur there is no evidence of the stimulus frequency. In my own case, at least, a stimulus strong enough to be extremely painful will generally force me to contract most of the leg muscles, but there seems to be no tendency to a definite movement of flexion or, indeed, to any fixed response. If the stimulus is a rhythmic series of induction shocks, the electromyogram from the tibialis anticus or the calf muscles shows nothing more than the usual irregular oscillations and differs in no way from the electromyogram of an ordinary voluntary contraction.

This result supports Hoffmann's contention that the "Eigenreflexe" or proprioceptor reflexes are in a class by themselves in that there is a much closer connexion between afferent and efferent neurones than there is in other kinds of reflex arc. This is suggested by the very short latent period, the absence of anything in the nature of momentum, inertia or fatigue, the absence of any change with strychnine, &c. Hoffmann's work shows that in man, with the brain in full control, the spinal motor neurones are directly accessible to the afferent impulses from the muscle; it is clear that they are much less accessible to impulses from the pain-fibres, although the connexion is close enough in the spinal animal with the brain destroyed.

We have, then, two possible factors which may help to determine the frequency of the electromyogram. One is a natural tendency of the spinal motor neurones to discharge at 50 a second when their excitability is raised by the cortical effect and they are not furnished with a ready-made frequency. The other is the tendency of the motor neurones to be influenced by afferent impulses from the contracting muscle itself—impulses which might well have a definite frequency determined by the mechanical properties of the muscle.

I have said little or nothing in all this about the application of the electromyogram to the problems of clinical neurology, but I have probably said quite enough to show that the interpretation of the curves is still far too uncertain for them to give much definite information. But I hope it has appeared that its investigation in movements of all kinds, normal and abnormal, may help enormously towards a real understanding of the electromyogram, and I hope it has appeared that such an understanding is well worth reaching.

THE PROBLEM OF MALIGNANCY

FROM A PURELY RADIOLOGICAL STANDPOINT.

A paper read before the American Medical Association at Atlantic City, May 27th, 1925,

BY A. E. BARCLAY, O.B.E., M.D., D.M.R.E. CAMB.,
PRESIDENT OF THE RONTGEN SOCIETY; RADIOLOGIST TO THE MANCHESTER ROYAL INFIRMARY.

"By Doubting we come to Truth."—*Cicero.*

"Who never doubted, never half believed,
Where doubt, there Truth is."—*P. J. Bailey.*

THE history of medicine during the last century is one of the great romances of the world, corresponding to that wonderful epoch in history when Columbus set forth on his voyage of discovery and the Portuguese, rounding the Cape of Good Hope, found their way to India and the East.

As in the sixteenth century, so to-day in medicine, whole new worlds have been opened up by those who, using the microscope and laboratory methods as their vessel of discovery, have navigated and charted the new worlds of science. Once more, as when the Spanish and Portuguese divided the known and unknown world between them, there is a dividing line, imaginary, no doubt, and on the one side we have the possessions and observations of the old order of naked-eye or macroscopic observation, and on the other the accurately mapped new fields that have fallen to the microscope. The mass of microscopic discovery has added so greatly to the sum of medical knowledge that to-day it is a human impossibility to master the whole of it, while the older macroscopic knowledge and observation have, by comparison, been almost eclipsed. Yet, with all the advances, there is one problem on which even the microscope seems to shed no new light—i.e., the cause of cancer—for in spite of all the world-wide research and the voluminous writings on the subject, the artificial production of growths in animals and plants, yet we know practically nothing more than our fathers as to the nature of human cancer.

New Type of Radiations.

In these last 29 years, however, a new light has crept in on this dread and growing scourge (300 per cent. increase in the last 70 years), one which has not, I think, received the consideration it should have done, especially from the microscopic point of view. Investigators of the problems of disease are all looking to the microscope to aid them in discovery, and the new type of radiations do not fall within its field of vision. In the case of cancer the eyes of all radiologists have been turned on the definite but elusive curative effects of the new rays and, may be, we have neglected to note " the writing on the wall " as we pushed onwards with more and more powerful radiations in our search for the *cure* of the disease. It always seemed that just round the corner lay the cure and increase of the penetration or quantity of the radiations applied would make all the difference. True, we have been disappointed, but it has made our outlook always tend towards maximum rather than minimum doses of this powerful agency—i.e., we have latterly tended to use radiation as a destructive rather than as a medicinal agency. We have written of our successes and failures in treatment, and of the tantalising uncertainty of our results, and we have recorded the radiographic appearance of cancer, but have we stopped to take stock and think what these things mean ? Have we turned to examine our observations from the point of view of the nature of the disease, quite apart from any thought of the cure ? Or have we *also* been content to take it for granted that the microscope, and the microscope only, is the chosen vessel of discovery ? When Columbus saw the failure of the Portuguese navigators in their search for the Indies, he decided to set sail in the opposite direction on his voyage of discovery, for it was obvious that the fabled Indies must lie somewhere. So, in like manner, I invite you to look in the opposite direction, to forsake the microscope and the assumption of its omnipotence, and to consider a variety of radiological and clinical observations for which I claim no originality or expert knowledge on the subject, and which are of the older microscopic school.

Under X ray and radium treatment the cure, or arrest of the progress, of some malignant growths is a definite fact, and we know with certainty that we have applied some factor which has altered the normal course of events. Many of the observations, however, are matters that are not capable of scientific proof, but are commonly accepted by those who practise radiation therapy. Others again are matters of surmise only, resting on no definite scientific data, in which, from long experience, one has a definite impression, a clinical sense, which may or may not be shared by others.

X Rays in Cancer : Contradictory Results.

Under the generic term " cancer " we include a number of diseases that are characterised by cell overgrowth, and that normally end in the death of the patient. The two great groups of the carcinomata and sarcomata are subdivided, by the microscope, into a number of less clearly defined varieties, but in the natural course of events they all carry the one definite common factor, death, as their ultimate termination. Some are rapid in their course, others less so. Some tend to extend locally only, others to rapid dissemination, and generally speaking the microscopic examination of the type of cell will give an indication of the prognosis. Yet every surgeon and every radiologist occasionally meets with an apparently hopeless growth that melts away as if by magic, while an exactly similar case, microscopically and macroscopically, runs its course entirely uninfluenced by the same treatment. In the early days of radium Wickham recorded the apparent cure of a carcinoma of the uterus with what would now be regarded as a futile dose, and almost every early worker with X rays had occasional incomprehensible and cheering results of the same order.

At the present time Wintz, quoting figures of his uterine and cervix cancer "cures," states that " in spite of the best technique, most favourable conditions and good general health of the patient, the results are from time to time inexplicable." He states that from 15 per cent. to 20 per cent. of absolute failures occur even in the cases in which his past experience would lead him to expect a successful result. Observers are generally agreed that, as a class, the malignant growths of the cervix are those which are most likely to yield a fair proportion of satisfactory results. The reason for this probably lies in the fact that in post-mortem examination it is found that 55 per cent. of these gynæcological cases show entire freedom from metastases, whereas breast cancer yields only 3·2 per cent. freedom from metastases in the post-mortem records (Lazarus-Barlow).

There are, however, evidently different types, histologically identical, at the one end of the scale those easily influenced by radiations, at the other those that are quite intractable—i.e., a radio-sensitive and a radio-insensitive type. Since all living tissues can be killed by destructive doses of radiations, all growths are classed as radio-insensitive which have the same or a greater degree of radio-tolerance than the surrounding normal structures.

The problem of malignancy as seen by the radiologist is full of contradictions, and it is clear that neither the clinical character nor the cell form of the constituents, although usually reliable, are the definite criterion as to the real nature of a tumour. For want of a better classification we must, therefore, still give the same name to histologically identical growths, although some of them disappear under radiations while others persistently extend and recur, regardless of all the wiles of the radiologist ; one cannot help feeling that there is some fundamental difference in the two, and that this difference is not expressed in the cells that are seen under the microscope. The one is a radio-sensitive and the other a radio-insensitive tumour. As yet the only means of determining the identity of each is by watching the effect of radiation treatment—an agency that may be applied in homœopathic, medicinal or such destructive doses that they " cure the disease and kill the patient."

Illustrative Cases.

Certain cases are landmarks in every medical man's experience, and the following are the only cases I shall mention in detail, for it is my purpose, as far as possible, to view things from such a distance that detail is lost. The first case was not labelled as one of the regular types of malignant disease, but out of it arose the train of thought which is embodied in this present paper.

In 1910 a healthy boy of 15, an only child, came with large masses of glands in the left groin and right side of the neck, and smaller masses elsewhere. The spleen also was slightly enlarged and it was diagnosed as a case of acute lymphadenoma, but it is just possible that it was a case of Mikulicz's disease. No changes were found in the blood at any time except slight secondary anæmia. He was treated with X rays and the glands disappeared. He went away to the hills but was back in a fortnight, gasping for breath, and with large masses in the mediastinum. These also quickly disappeared, but the boy, though apparently well again, was kept under observation and frequent treatment. Glands appeared from time to time in all the usual sites but were always easily disposed of.

There was some swelling of the hands and feet and these became exceedingly painful. Radiographs showed definite changes in the bones of one of the hands, and these I shall refer to later. X ray treatment cured the pain and swelling completely and he could dress himself and use ordinary boots. But gradually the boy lost strength in spite of the fact that every gland disappeared under treatment almost as soon as it was detected. Hundreds of lymphoid nodules appeared in the skin of the back and in other situations, some breaking down and forming ulcers about ¾ inch in diameter, and these also yielded to the magic. When only a portable coil and accumulators were available even the masses in deep situations yielded. Yet all the time the weakness and slight cachexia increased, and after 15 months of the toughest medical fight I ever had he died from exhaustion. It was one of the most disheartening cases imaginable, for the faith of the parents and son was kept up the whole time by the effects of the rays, and yet to the onlooker it was obvious that it was only the glands and nodules, the symptoms, the accidental factors, that were influenced. There was evidently some underlying cause at work that we were not touching at all by our radiations. In this case, at any rate, it was perfectly clear that there was a definitely *malignant disease* at work, of which the lymphoid overgrowths were but a symptom. Without X rays the glands would have wrought death, accidental, as I term it, in a few weeks; but with treatment the accidental death was averted and we had the picture of the underlying malignant disease running its slow and certain course, unaffected in any way by the rays. The outstanding impression on my mind was the fact of an underlying *malignant disease* which was giving rise to enormous overgrowth of all lymphatic tissue, these overgrowths being practically malignant growths, although they did not tend to invade surrounding structures.

And then on the other side of the picture are two very early private cases, clinically almost identical so far as one could see, in which the diagnosis was retroperitoneal sarcoma originating in the suprarenals.

In one case, a boy of 9 months, no operation was performed. In the other, a girl of 15 months, the late Prof. G. A. Wright explored, found a typical sarcomatous mass that was friable and almost breaking down, and which he did not attempt to remove. Both these infants were irradiated with such apparatus as we had in those days—at the most the tubes would not stand more than half a milliampère at perhaps a 3-inch to 4-inch spark gap. There were no filters except a layer of felt, and the skin was hardly bronzed. Yet both these children recovered completely and are now normal healthy young adults. What had wrought this change ? I know not, but it was quite certain that these malignant growths were affected by something, presumably the rays, in spite of the fact that so little could have reached the required depth. And the impress of these two cases on my mind was that of a locally *malignant growth*, fortunately of an unusually radio-sensitive type, in which the originating cause had disappeared.

From these isolated and rather unusual cases, therefore, I came to looking at cancer cases in a different light. It occurred to me that perhaps a *malignant growth* might be originated by a *malignant causative disease* and that these two elements might exist concurrently, or that the malignant causative disease, having started the malignant cell overgrowth, might die out, leaving the malignant growth to accomplish the death of the patient, but thwarted in the case of these two infants by the fact that the growth was particularly radio-sensitive and that there were no untreated metastases.

There is one, and only one, certain proof of malignancy—i.e., the death of the patient—for neither the clinical nor the microscopic characters of the cells are infallible evidence of malignancy. If a patient recovers from what was clinically and microscopically a malignant growth, we write it down as either a miracle or that the diagnosis was wrong. One man put it that the radiologists' successes in cancer were the clinicians' failures in diagnosis, but this is far too sweeping and is not justified by experience, for these miracles are too frequent and too dramatic to be interpreted in this way. If the patient recovers, however, we can never say with certainty that he had been suffering from a malignant disease, for death is the one and only infallible proof that the process that we have been watching or treating is a malignant one. No clinical and no microscopic evidence is infallible. Microscopic malignant cell form and malignancy are not necessarily synonymous terms.

Different Causes of Death.

Death is the natural end-result, the one common factor, but the manner in which life is extinguished differs very widely and calls for more than passing consideration.

The first and far the commonest cause of death is that some vital organ is invaded by the direct extension of the primary growth or its metastases. This form of death is accidental and not an essential part of the malignant disease, for it is something approaching pure chance whether the growth attacks a vital part early or late. A very malignant type of growth in one part of the body may take a long time to kill the patient if situated in some less vital spot. One could, in fact, imagine a growth extending almost without limit, provided it maintained its blood-supply, if it did not invade a vital organ.

Secondly, there is death from septic infection with its resulting absorption, its cachexia, debility, and gradual wasting. This again is not an essential part of the malignant disease, although death supervenes. Within the body this source of danger to life is still only too common, but, thanks to X rays, we see less and less of this type of death from external ulceration, with its festering and fœtid ulcers.

The third and much more unusual type of death suggests that as in my lymphadenoma case there is another factor, one of which I have no proof, but of which I am fully convinced. We see some devitalising process at work and we usually attribute it to the effects of undiscovered secondary deposits, but in many cases I feel certain that it is largely the manifestation of an underlying malignant disease which unfailingly results in the gradual weakening of the patient, with cachexia, loss of energy and strength, and which ends inevitably in the death of exhaustion. Whenever we see a cancer patient with cachexia, apart from septic absorption, we know that, no matter whether the mass responds or does not respond to X rays, the patient will steadily go downhill and die, and in the terminal stages the temperature will rise, quite apart from the presence of any sepsis. This, to my mind, is the manifestation of the working of the true malignant disease. Provided the patient lives long enough this process is seen in varying degrees of intensity, but is always subject to the intervention of death from one of the intercurrent or "accidental" causes—invasion of vital organs or sepsis. It is seldom, if ever, seen in rodent ulcer, but its presence is often suggested in those forms of malignant disease of slow growth in which metastases are not attacking vital organs, and it gives one the impression that the ordinary causes of death in these diseases (extension and sepsis) are not only accidental, but that many of these growths are only an incident or accident in an underlying malignant disease. In order to save repetition I will call this hypothetical and entirely unknown quantity, this essential underlying malignant process, x, and I may as well say at once that I believe it will eventually be found in the blood, that it may disappear after originating the growth, and also that it may vary widely in intensity, quite apart from the type of growth it evokes.

The Unknown Quantity.

I believe that this x occurs in every case of true malignant growth, and yet, how can one explain the fact that certain cases are cured by surgery or by radiations, while others persist and spread, either directly or by metastases, in spite of all we can do ? Think of a case of a rodent ulcer that fails to respond. The patient often remains in perfect health until sepsis or extensions slowly end the scene. It is a purely local disease and there seems to be no x in the case at all. It is merely a locally malignant disease and one which, mercifully, is usually radio-sensitive. It does not even tend to extend by metastases but only by direct spread. If x was ever present in the case, it has disappeared.

Now look at the type of breast growth in which all the conditions seem to be particularly favourable for operation, so far as the surgeon can tell. In some of these a recurrence comes in or about the scar, which may respond perfectly to comparatively mild X ray treatment, and we see an apparent local cure. Unfortunately, however, there are only too often secondary deposits elsewhere that we cannot detect, and these are usually the "accidental" cause of death, and yet one feels practically certain that if these patients had been irradiated early enough there would have been no metastases and we should have obtained an actual cure, as we actually do in a considerable number of such cases. Occasionally one has the good fortune to treat a case of this type that is not complicated by operation. I see a woman from time to time who five years ago had a large and typical inoperable scirrhus with extensive glands both in the axilla and above the clavicle, and yet to-day the patient is in perfect health, and there is not a sign of any previous disease in the breast. In another case the breast became almost normal under radiations in the period of waiting for a bed in the hospital. The obvious thing to say, of course, is that the diagnosis was wrong, but a large number of what must have been similar cases, in which the surgeon states that he has been able to remove only a portion of the growth, are alive and well to this day. The cases are far too numerous to be accounted for by throwing doubt on the diagnosis of the clinician and microscopist. I interpret these very encouraging results by thinking of them as of only local malignancy, apart from metastatic spread. They happen to be radio-sensitive and we obtain an apparent cure; the cause, the *x* that originated the growth, has disappeared, and if the growth is completely eliminated by operation or by radiations or by a combination of the two an actual cure is effected.

Then one thinks of other radio-sensitive cases in which although recurrences disappear under the rays, others come up, and often we are also successful in dealing with these as they occur—the cause, the *x*, is still at work and sooner or later death comes, usually by internal deposits in vital organs and sometimes accompanied by the cachexia, &c., that is associated in my mind with *x*.

Radio-insensitive Cases.

But among those cases that seem to offer every prospect of success, and which are irradiated at the earliest possible moment after operation, there are some in which growths appear in or about the scar and which are quite uninfluenced by the rays—i.e., radio-insensitive. They spread by direct extension in spite of all we can do. Occasionally a change in the type of radiation raises our hopes for a time, but, nevertheless, death comes, generally by metastases. And yet, this absolutely uncontrollable, radio-insensitive disease seems to differ in no outward or microscopic characteristic from the other type which is radio-sensitive and which, apart from metastases, seems to promise such good results.

In many of these breast cases, however, in addition to the growth there seems to be some other factor at work. The tumour itself may have the same clinical and microscopic appearance as those in which we have obtained apparent cure, and it may or may not respond locally to radiation; but no matter what we do, there is the gradual wasting associated with cachexia which is, to my mind, evidence of the true underlying malignant disease, which when once established never seems to falter in its course, but unfailingly brings death no matter what happens to the growths, the cell overgrowth that takes place in its presence. The patient gets weaker and weaker, develops a temperature, and eventually dies from exhaustion, occasionally with so little of the cancerous growth itself that it looks very doubtful if the tumour could have been the cause of death. In its course it resembles a case of pernicious anæmia, complicated by a growth.

In some of the breast cases one can trace the same course of events as in the lymphadenoma boy, but less accurately and in a much more complex picture that is distorted and obscured by the malignant tumour and its symptoms. Sometimes one gets a clear impression of the underlying cause at work if the growth happens to be radio-sensitive, and we note the progressive weakness, which we usually ascribe to internal secondary deposits. I suggest, however, that, in part at least, it may be put down to the continued action of my hypothetical *x*.

I have chosen to speak in terms of those types of cancer which are most common and most easily observed, but my general impression of growths in other situations is on the same lines—i.e., that there are two distinct types clearly differentiated by the manner in which they do or do not respond to radiation. Some are much more susceptible than others in their reaction as well as by reason of their accessibility, but underlying and at the back of all of these there is a malignant causative disease, which may or may not persist after it has done the deadly work of initiating the growth.

In the radio-sensitive type we may hope for complete success if we can locate and heal the primary focus and its metastases, only if this underlying factor has disappeared, but if *x* is still at work, even in a very mild form, we shall not succeed in the end, for sooner or later recurrences, even if they are of radio-sensitive type, will come where we cannot detect them, and death follows. In the radio-insensitive type we can do nothing but watch the progress of the growth and its metastases. When *x* is *not* at work one has seen these tumours pursuing their tragic course for a year or more, with comparatively little, if any, lowering of the patient's vitality, till nerves are involved, when pain and loss of sleep undermine the patient's strength. The end in such cases is often pathetic, and it is a merciful release when, at last, some vital organ is put out of action.

In those cases which I suggest are due to the persistence of the true malignant cause, *x*, the picture, if we can eliminate the obsessing factor of the growth itself and its symptoms from our minds, is one of increasing debility, of the type of pernicious anæmia, and it is this disease which I would suggest to your minds as the simile of the underlying malignant disease. This fatal type of blood change is not associated with cell overgrowth, but you all know how frequently a case diagnosed as pernicious anæmia turns out in the end to be "due" to an internal growth. I suggest that in these cases of mistaken diagnosis we may have been confusing cause and effect, and it is possible that some of the cases of so-called pernicious anæmia are the uncomplicated action of my hypothetical *x*.

Is X a Blood Condition?

I suspect that this *x* is a blood condition, possibly a very delicate biochemical change that has a selective stimulating action on the growth of certain types of cell under favourable conditions, the type of cell affected depending on the nature of the biochemical change. Of the conditions we know nothing, but if one might indulge in pure speculation for a moment one might accept *x* as a temporary or permanent blood condition, very slight changes determining whether its action should influence one or other of the different types of cell to cancerous growth. Suppose that at the time this slight blood indisposition occurred there was irritation of, say, the breast cells by some course, it might stimulate these cells to disordered overgrowth, forming a malignant tumour that would normally run its fatal course, while the underlying malignant disease, the blood change, entirely disappeared. The patient is operated on and there is a "cure." One could imagine the same sequence of events occurring again after many years, and surely this is a more reasonable explanation than to think of malignant cells lying dormant for perhaps as long as 20 years.

Or we may suppose that the malignant disease in the blood gets a strong hold, and no matter what treatment the growths receive as they appear the cause will still be at work, stimulating other groups of cells of the same type into activity, for its selective action is most definite. At the same time each of these growths is capable of dissemination in the various well-recognised ways, and before the malignant disease makes its presence known as a separate entity the growth has completely filled the picture. Suppose, however, x does not find any injured cells on which to act, or maybe the blood change does not happen to be one that affects any particular type of cell until very late, then we get the picture of the cases that approximate to pernicious anæmia.

This, of course, is all pure fantasy and put down simply to give more concrete form to my rather nebulous ideas as to the nature of x. It is, however, a most remarkable fact that a patient seldom suffers from two types of cell overgrowth at the same time. Scirrhus of the breast and similar types of growth elsewhere, colloid, columnar, squamous, round or spindle-celled overgrowth, many are the types, but only one type as a rule in one patient.

In the boy who forms the subject of my text the malignant disease disordered the reproduction of the lymphoid cells first in one region then in another, and later on practically universally, but never any other type of cell. Because these happened to be radio-sensitive we could watch the almost undisturbed progress of the malignant disease itself. In breast cancers it is only too common an occurrence to find the other breast affected, and with a cellular formation that is identical with the first growth.

A Reasonable Hypothesis.

Thanks to our teaching we are so taken up with the idea that all secondary manifestations arise from the one primary growth, and that the cause of the growth is contained in the mass itself, that we do not think of the possibility of some outside cause that may stimulate similar cell elements in other parts of the body and that some of them may be entirely independent growths originated by the same cause. To my mind the hypothesis I have suggested gives a much clearer idea of those unaccountable metastases that we could not explain on any reasonable grounds. We will all accept that a metastatic deposit may travel by the blood-stream, and we must accept that the lymph-stream carries the trouble along its course in the direction of its flow. We must also accept the fact that a growth creeps, say, across the middle line from, say, the breast, and we can trace the nodules in the course of spread by direct extension. And yet we see many cases of recurrence on the opposite breast, often in the outer upper quadrant, with not a trace of intervening growth. It is not just an occasional happening; it is a thing we are always looking out for, and the only explanation that is given is that it is lymphatic extension *against* the flow of the lymphatic stream. Such an explanation is against the laws of physics and experience, and I suggest that my hypothesis offers a much more reasonable explanation. The x that caused the original trouble is still present or has recurred, and it has affected another group of cells of the same class, stimulating them to malignant activity.

In one such case that I saw after writing this I noted three things. The right breast had been removed and there was (1) direct extension of small nodules in the skin across the middle line and elsewhere; (2) a large mass in the upper outer quadrant of the other breast with glands in the axilla; and (3) another curiously placed and much larger recurrence well below the scar. This last was puzzling till I thought of the possibility of a rudimentary breast in such a position. I believe that in this patient x was still at work, and in addition to the frequently noted stimulation of a growth in the other breast it had affected the rudimentary breast cells in addition, and that these two centres of growth were not recurrences in the ordinary sense but actually new primary growths set up by the same unknown factor that had initiated the original breast tumour. Is it not reasonable to suggest that the cause which originated the primary growth may still be at work in these cases and that it may set up a similar type of growth in other parts that contain the same cell formation?

There are relevant observations on post-operative breast treatment, blood changes, and manifestations in bone that give credence to the theory I have put forward.

Does this Theory Help Us in any Way Towards the Elucidation of the Great Problem?

I think that it does, for it suggests very strongly that it is waste of time and energy to look for the cause of cancer by gazing down a microscope at the sections of a cell overgrowth, and the end-result of a factor that may or may not have been present when the specimen was taken. That, perhaps, is a negative benefit. It does, however, indicate that if we are to find the cause we must sift our cases and attempt to determine accurately in which of these x is still at work and find out in what way the blood differs from those in which the disease is only locally malignant—i.e., in which x is no longer present. It is among the living, not among the dead, that hope lies. Certain observations as to changes in bones make me confident that the cause of malignant cell overgrowth is a systemic one, and the obvious inference is that it will be found in the living blood. Until we know with certainty in which cases x persists, we must search every cancer case and particularly attempt to find a difference in the blood between those that develop the ill-omened cachexia, as compared with those in whom the disease is only locally malignant as shown by operation or radiation "cures."

I am quite satisfied that it is useless to look for the cause of malignant disease in the growth itself, and that the exciting cause will eventually be found elsewhere, either in the blood or carried by the blood, and that it will probably be found in some minute bio-chemical change which affects the reaction of the blood upon certain types of cell, those cells being particularly susceptible that have suffered from some mechanical or inflammatory source of irritation or which in the natural course are undergoing degenerative changes at the end of their life of functional activity.

A Summary.

It is a usual custom to summarise a paper, and I am indebted to my partner, Dr. J. M. Woodburn Morison, for the following which he handed to me after reading an early manuscript:—

Let x be the underlying cause of cancer.
,, G ,, a tumour that is radio-sensitive.
,, D ,, the death of the patient.
,, L ,, ,, life ,, ,, ,,
,, O ,, ,, operation.
,, R ,, ,, radiation treatment.

$$\text{Then } G + x = D$$
$$G - x = D$$
$$\left.\begin{matrix} G + x + R \\ G + x + O \end{matrix}\right\} = D$$
$$G - x + O = \frac{L}{2}$$
$$G - x + O + R = L$$

Therefore, the only cases in which we can hope for cure are those in which we have a radio-sensitive tumour, an absence of the underlying cause, and complete extirpation either by operation or by radiation or by a combination of the two. If, however, a growth is radio-insensitive there is no chance at all unless, perchance, a surgeon is fortunate in removing the whole of a growth and x is no longer present.

In conclusion, I wish to acknowledge the very great assistance I have received, wittingly and unwittingly, from many of my colleagues, particularly those who collaborate with me in the X ray work of the Manchester Royal Infirmary, Dr. Morison, Dr. A. Burrows, Dr. R. S. Paterson, and Dr. E. W. Twining.

CUTANEOUS MYIASIS IN MAN CAUSED BY *MUSCA DOMESTICA*.

By W. S. PATTON, M.B., CH.B. EDIN.,
MAJOR, I.M.S. (RETIRED); LECTURER ON ENTOMOLOGY AND PARASITOLOGY, EDINBURGH UNIVERSITY;

AND

H. A. COOKSON, M.B., CH.B., F.R.C.S. EDIN., D.P.H. CAMB.,
PATHOLOGIST AND BACTERIOLOGIST, SUNDERLAND ROYAL INFIRMARY, ETC.; EXAMINER, D.P.H., ROYAL COLLEGE OF SURGEONS, EDINBURGH.

THE case of cutaneous myiasis about to be described is of peculiar interest, because, as far as we can discover, the larvæ of *Musca domestica* have not within recent years been recorded from the subcutaneous tissues of man. It is true that the larvæ of this fly are not uncommonly found in the human alimentary tract and even in the bladder, but the subcutaneous tissues is a most unusual place to find them. It is also interesting to note that although there were many larvæ in the legs they produced little or no discomfort, and apparently no secondary destruction of tissues. Had the tissues of the leg been invaded by the larvæ of a species of *Sarcophaga*, or by either of the screw-worm flies, *Chrysomyia macellaria* or *Chrysomyia bezziana*, there would have been extensive and serious destruction of tissues.

The patient was a man of over 80. He had chronic bronchitis and varicose veins of the lower extremities. Owing to the bronchitis it was not possible for him to lie down, and he spent most of his time sitting in his chair in front of the fire. The legs were bandaged. In June, 1924, he noticed above the right internal malleolus a small "hole," and he confessed to having rubbed his leg. He had the dermatitis so often associated with varicose veins. Shortly afterwards "maggots" were noticed on his leg, and the patient stated that he thinks the first maggot emerged from the small cavity above the malleolus. On their first appearance they remained for a day or so, and then were not observed for three weeks. After this they appeared at intervals until Dec. 15th, when the last specimen was seen. The right leg only was affected in this way. Below the knee the skin was inflamed, thickened, and moist, its surface being denuded of epithelium and raised into small elevations with somewhat deep crevices between them, and in one or two places there were little cavities. When the dressings were first removed on the occasion when the photograph was taken (see figure) only one or two larvæ were seen, but in a few moments the leg became alive with actively moving maggots. They appeared to exist in the small crevices and holes described. The condition gave the patient no inconvenience; indeed he was interested in his strange infection.

Characters of the Larvæ.

A number of the larvæ were collected in September by Dr. A. B. MacPherson, and preserved in 4 per cent. formalin. On examination later they proved to be the first and third instars of the larva of *Musca domestica* L. The following notes are given in the hope that they will be of some use to medical men who may come across the larvæ of this fly in the human body.

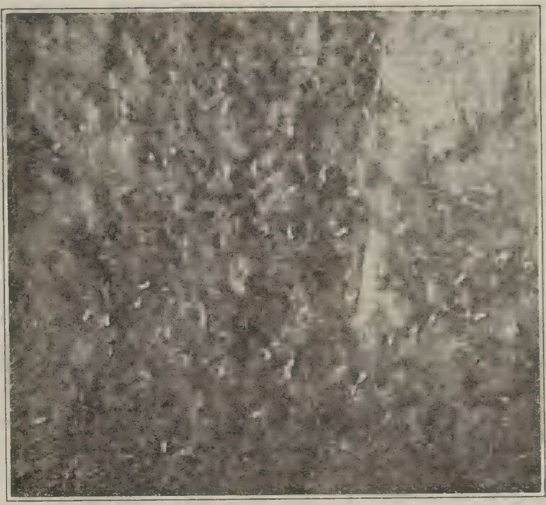
First Instar of the Larva of Musca Domestica.—This stage can always be recognised by the small size of the larva, the absence of the anterior spiracles (a character common to all the first-stage larvæ of the higher Diptera), the structure of the cephalo-pharyngeal skeleton, and the structure of the posterior stigmata. It will be noted that the pharyngeal plates are narrow and have a characteristic crescentic outline posteriorly, the dorsal and ventral processes or horns being well developed. There is a simple median mandibular hook, two well-developed spines, and many smaller ones on the skin in front of the oral opening. The posterior stigmatic openings are on slightly raised papillæ, and each is heart-shaped and has a single opening; there are a few small spines on the rims. In this stage there is a small belt of spines at the anterior end of the ventral surface of each of the eight posterior body segments.

Third Instar.—All the external and internal structures of use in identification are, in this stage, well developed. The anterior spiracles have from five to seven finger-like processes each with an opening at the end; it is not uncommon to find that the number of these processes varies in the same larva on the two sides. The cephalo-pharyngeal skeleton is well developed. As first pointed out by one of the writers, the mandibular hooks are unequal in size, the left being much smaller than the right. In all previous descriptions of the hooks of the third-stage larva of *Musca domestica*, and in all the excellent models on exhibition in public museums, only one hook is described and shown. There are, however, always two, and the left is very commonly obscured by the right if it is looked at on its side. This character is important in identification; it is common to the species of the genus *Musca* as well as to the larvæ of species of *Stomoxys*. The shape of the pharyngeal plates is also very characteristic, and especially the deep notch on the posterior surface.

The first and third stage larvæ (and, as a matter of fact, the second stage as well) can be readily distinguished from the same stages of other larvæ of the higher Diptera, which are likely to be found in human tissues, by noting the characters mentioned above.

Commentary.

From the notes of the case it seems clear that a female *Musca domestico* deposited its eggs in the vicinity of the "small hole," the ulcerous cavity, mentioned above early in June. Towards the end of the month the larvæ were noticed on the surface of the leg, and the patient noted that the first larva emerged from the cavity near the internal malleolus. The larvæ were noted for a day or two, and then they disappeared, to return at intervals of about three weeks or so; one larva was observed as late as Dec. 15th, 1924. The illustration shows the larvæ on the surface.



Reproduction of photograph of the diseased limb, slightly enlarged, showing the larvæ.

There are one or two points to which we would like to draw attention. First, we have no doubt that all these larvæ came from the eggs laid by a single fly. The fact that they continued to emerge at intervals for months is, we think, explained by noting that the larvæ of *Musca domestica* never flourish in either living or dead tissues. It is an unsuitable medium for them, and in this case they continued to emerge to the surface, evidently endeavouring to leave the leg. Some of the larvæ reached the third stage, but they were very small and incompletely developed specimens, and had these been allowed to pupate they would have given rise to very small flies. None of the larvæ collected had reached full growth, although they had been in the tissues of the leg for weeks. In confirmation of this view we may point out that one of us has tried to breed the larvæ of other species of *Musca* in the dead bodies of animals, but never succeeded in getting well-developed flies.

We wish to thank Dr. A. B. MacPherson, of Sunderland, under whose care the patient was, for his help and giving of facilities for observing and recording this strange case.

THE ARTIFICIAL INDUCTION OF LEUCOCYTOSIS.

BY BURR FERGUSON, M.D. COLUMBIA, N.Y.,
U.S. PUBLIC HEALTH SERVICE, SOUTHAMPTON.

With Addendum by

G. R. SEAGER THOMAS, M.B. CAMB., M.R.C.S. ENG.,
HON. PATHOLOGIST, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.

SOMETHING over a year ago it was suggested by work in the Municipal Laboratory of Southampton, with the aid of the former borough pathologist, Dr. Harry Simson, that the intramuscular injection of salicylate of mercury is followed by a marked increase in the production of white blood cells, which I took to explain the potent influence of this drug on certain manifestations of syphilis, on furunculosis, and small infected wounds. In the treatment of the latter infections good results have been obtained for about eight years in various parts of the world. The drug was used in the belief that the mercury was having its so-called specific influence on the treponemata, and that I had been fortunate in finding this effect extended to the pyogenic organisms. To me the knowledge that the oldest drug we know induced an increase of white cells seemed logically to explain its satisfactory action in syphilis, as well as in the other conditions. It is a matter of common knowledge that a man in the best condition has a high white cell count, and can stand exposure best to infections. When harmful infecting organisms do find lodgment, there is, in most infections, an immediate rise in the white cell count, these cells being directly involved in resistance.

At my suggestion encephalitis lethargica in the City Hospital, Fazakerley, Liverpool, is said to have been successfully treated in application of this principle by Dr. C. Rundle, officer in charge, and his staff, 39 cases being given an average of four injections each of gr. 1 of the salicylate of mercury in oily suspension. All recovered satisfactorily save one; in some the improvement is said by Dr. Rundle to have been striking. One patient who came in on the ninth day of the infection died after having had one injection.

Thirty-one cases of trachoma among Poles and Russians who were detained because of this infection at Atlantic Park, Eastleigh, Hampshire, have been treated by Dr. Frank McGee, the medical officer in charge, and by Dr. Arthur Zorab, of the Eye Hospital, Southampton, as consultant. Treatment by an induced increase of leucocytes was begun in November, 1923. In March they began to be passed as cured of trachoma by all examining officers here and in New York and in Montreal. So far there have been 25 of the original 31 cases declared cured and are now residents of the United States and Canada. These cases had from 12 to 35 injections of salicylate of mercury. Four of the remaining cases are having N.A.B. with good results, as will be told by Dr. Seager Thomas. The usual local treatment—rolling the lids with application of copper sulphate and a 1 per cent. solution of perchloride of mercury—has been used, together with the injection of salicylate of mercury, given once a week during periods of six to eight weeks. A rest was given to allow the individual to re-establish a sensitiveness to the mercury, as with each successive dose or injection the rise in the white cell count is diminished, finally becoming negligible after six or seven weeks—no increase in white cells and no noticeable change in the trachomatous lesion. This seems to me to be the logical reason for our early instruction that in the treatment of syphilis mercury must be given in series or courses. After a rest the administration of mercury was followed again in the trachoma cases by improvement, blood counts showing rapid decline in the effect of the stimulation on the production of white cells after repeated injection of the drug.

In an attempt to extend the principle of the treatment of infections by induced increase in white cells I have seen or known of rapid, certain, and satisfactory results in arthritis, asthma, bronchiectasis, pyelitis, acute otitis media, eczema, not yet diagnosed abnormalities or infections of the skin, iritis, iridocyclitis, carbuncle, and hay fever, after one to three injections each. Last spring a friend had his fourteenth recurrence of hay fever, with the conjunctivitis, congested nasal membranes, cough, sneezing, and ordinary discomfort of the infection. On the day I saw him he had used seven handkerchiefs. An injection of salicylate of mercury was given and I saw him 24 hours after. There was no evidence of any irritation about the eyes, no swelling of the nasal membranes, his breathing was clear, and he proudly showed, still folded and not used, the four handkerchiefs with which he had provided himself on leaving his home in the morning. I communicated with Dr. Zorab, who said that he had just used salicylate in two cases of hay fever with equally good results, and to better effect, for there was no return of the infection in his cases, while the infection returned in my friend in six days, though it was not so severe as at first. A second injection of salicylate was not so potent, and his discomfort continuing, on the third day of the recurrence N.A.B. was given, when he grew rapidly better and had, he said, his best year for 14 years.

The belief that novarsenobillon and quinine derived their potency from their power to stimulate the production of white cells became so strong, that I consulted Dr. Seager Thomas at his laboratory. He will tell of his findings.

The promise of a satisfactory extension of the principles seems great in many directions, but experience can here be the one guide to an opinion.

Addendum by Dr. G. R. SEAGER THOMAS.

There has recently been a fairly considerable use of salicylate of mercury in a more or less empirical manner for the treatment of a variety of conditions, notably trachoma, staphylococcal infections—e.g., furunculosis—and encephalitis lethargica. The major portion of this therapy has been somewhat spasmodic and disconnected, but for many years in several quarters of the globe salicylate of mercury has been used consistently in many different types of case by Dr. Burr Ferguson of the U.S. Health Service. Dr. Ferguson's communication above refers to his experiences in this direction and to that article these notes are simply a pathological postscript.

His successes with mercury, to which he refers as one of the "specifics," led Dr. Ferguson to attempt the substitution of novarsenobillon or alternatively quinine for the mercury. His results need not be again described here. Finding that similarly satisfactory effects followed the use of these drugs also, he felt that an hypothesis to explain provisionally the rationale of the treatment would be of interest and value. His observations led him to the belief that these drugs owed their efficacy to a power of artificially inducing leucocytosis.

This view led to a certain amount of amicable controversy, and the writer, on being offered the opportunity of investigating the leucocyte variations in a number of subjects, considered that it would be only sensible to test Dr. Ferguson's hypothesis by a rigid application of the scientific method. The first stage—recording of observations—is supplied by Dr. Ferguson's own and other medical men's records of the cases. The second stage—formulation of a provisional hypothesis—is supplied by Dr. Ferguson's suggestion that the drugs act as inducers of leucocytosis. It next becomes necessary to perform a number of carefully controlled experiments, record the results, and see whether these are in accordance with the provisional hypothesis. The work is in active progress now, and an indication of the results obtained is the purpose of this communication.

Should the results obtained support the provisional hypothesis, or a modification of it, then we can be said to have a theory of the action of these drugs, and such a theory should be capable of application (1) satisfactorily to explain apparent exceptions, and (2) accurately to predict the influence of one of these drugs upon the blood picture in a given case. Such applications of the theory, if successful, constitute scientific proof of its correctness. Both these exercises have been performed.

The reason for publishing any of the laboratory findings at this admittedly early stage of the investigation may not at once be clear. It has been reported that several laboratories in Germany are busily engaged in the search for an agent for the artificial induction of leucocytosis. It seemed therefore not unwise to record the fact that an investigation into just such properties possessed by well-known drugs had already been initiated. It is not claimed that the necessary experiments, observations, and correlation of the results are as yet in anything but the very earliest stage.

I have myself seen a number of successful cases, most of which were treated by novarsenobillon (there was no reason to suggest syphilis, nor was the drug administered for this disease). A series of cases of trachoma was amongst those which made the most vivid impression. There is, however, no intention to refer to the purely therapeutical aspects of these cases here, as favourable testimony from this point of view is forthcoming from clinicians.

An indication of the hæmatological results is given below:—

TABLE I.

Subject.	White blood cells per c.mm.		Subject.	White blood cells per c.mm.	
	Before intramuscular administration of 1 gr. mercury salicylate.	24 hours later.		Before intramuscular administration of 7½ gr. of quinine bihydrochloride.	24 hours later.
D. M.	7,000	20,400	J. M.	11,000	14,000
M. P.	8,000	17,000	C. P.*	9,300	12,700
M. C.	18,600	21,800			

* 5 gr. only given.

TABLE II.—*Effect of Intravenous N.A.B. (Dose varies from 0·3 to 0·6 g. according to Size of Subject).*

Subject.	Before N.A.B.	24 hours later.	7 days later.*	24 hours later.	7 days later.
	White blood cells per c.mm.				
B. F.	7,200	10,200	9,800	—	—
J. M.	10,400	22,800	21,800	—	—
C. P.	7,200	10,200	9,300	—	—
K.	7,600	10,600	12,400	17,100	14,600

M. G. ..	10,000	14,000	12,000	—	—

* Second injection given on seventh day.

It will be seen from the tabulated results that mercury, quinine bihydrochloride, and novarsenobillon are powerful inducers of leucocytosis. The investigation with regard to quinine was not continued for the following reasons: (1) The injection is distinctly painful, and (2) it appeared to have no advantage over mercury or N.A.B.

Previous leucocyte counts carried out for Dr. Ferguson (at other laboratories) have shown that a tolerance to mercury is somewhat rapidly established, the leucocyte count returning early to normal and being comparatively little raised by repeated injections. In novarsenobillon we have an agent practically painless in administration and at least as safe as either of the others in suitably selected cases. Its first effect upon the leucocyte count is at least as marked, its period of maintained leucocyte increase much longer, and its effect at repeated injections very much greater and more constant than in the case of the mercury and the quinine. There seems to be very little doubt that in novarsenobillon and its variants we have a very constant and dependable agent for inducing leucocytosis, where this is desirable.

One of the apparent exceptions was a case in which the count before injection of novarsenobillon was 17,000 per c.mm. and 24 hours later had dropped to 12,600 per c.mm. The result, however, had been anticipated as one of two probable results of the injection. The subject was a patient who had a very large acute "boil." It was anticipated that either (1) the "boil" would discharge completely within a few hours of the treatment, thereby rapidly removing the cause of his natural leucocytosis, and producing a drop in the count, which, however, would be artificially prevented from returning to normal; or (2) he would have added to his natural a further artificial leucocytosis if the "boil" still persisted as a focus of pus under pressure, and yield a count somewhere near 25,000.

In order to explain sundry cases where the customary relief does not occur I have suggested a modification of the simple "leucocytosis theory" of Dr. Ferguson. It seems but reasonable to believe that however successful one may be in inducing leucocytosis, the army of phagocytes will be ineffective if unattended by munitions of war, the multifarious "antibodies," and it is now proposed to observe the effect of the administration of novarsenobillon to patients whose specific antibody formation has been stimulated by autogenous vaccines. It appears to me a more sound rationale to bend to one's purpose not the cellular alone, but also the humoral factors of immunity.

At first differential white cell counts were made, but it was soon seen that with very slight exceptions (in one or two cases there was slight eosinophilia, in others increase of endothelial cells and occasionally some polymorph increase) the variations in the relative counts remained within the limits of the normal. The differential counts were then discontinued.

These investigations will take time, but in due course the complete record will be to hand. It appears to be a promising field in which laboratories having at their command a greater abundance of material than is at our disposal here could find a very valuable sphere of activity.

NORTH STAFFORDSHIRE INFIRMARY.—On June 5th the King, who was accompanied by the Queen, laid the foundation-stone of extensions to this hospital at Stoke-on-Trent, which serves a population of close upon half a million. A large addition is being made to the nurses' home and a new ward unit provided; the preliminary work for further enlargements is also being done. The cost will be £150,000, and it is claimed that when the enlargements are completed the North Staffordshire Infirmary will be the largest hospital outside London. It dates from 1815, when it was established at Etruria, but it descends also from a dispensary started in 1802. It was rebuilt on the present site at Hartshill in 1869, the foundation-stone having been laid by King Edward when Prince of Wales.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—Dr. Edward Hindle, Milner Research Fellow of the school, has been granted leave of absence for two years in order to undertake, in conjunction with Major W. S. Patton, an investigation on the transmission of kala-azar in North China, on behalf of the Royal Society. During the past six months Dr. Hindle has been working on the biology and life-history of spirochætes, and has investigated the prevalence of leptospira in the neighbourhood of London. He has been successful in finding these organisms not only in Thames water, but in tap-water, and many other sources. On his way East Dr. Hindle is calling at Calcutta in order to see the work of the Indian Kala-azar Commission. Whilst in China the Kala-azar Commission of the Royal Society will have a central laboratory at the Shantung Christian University, Tsinan, where Dr. Hindle expects to arrive in the autumn.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FEVER HOSPITALS MEDICAL SERVICE GROUP.

AT the annual meeting of this group, held at the Society's house in London on May 22nd, a discussion took place on the

DICK REACTION AND THE SERUM TREATMENT OF SCARLET FEVER.

Dr. E. W. GOODALL (N.W. Fever Hospital, Metropolitan Asylums Board), Vice-President, occupied the chair.

Dr. R. A. O'BRIEN (Wellcome Physiological Research Laboratories), in opening the discussion, said :—

I should like to give some short account of what progress has been made in England in the application of the results obtained in America, notably by the Dicks, Dochez, Park and Zingher. But I would prefer to draw your attention at greater length to the difficulties ahead and the urgent problems awaiting solution before much progress can be made.

Progress in England.

Dick Test.—The results obtained in England, such as the series published by Okell and Parish in July, 1924, and April, 1925, and the longer series by Ker (THE LANCET, 1925, i., 230), as well as a number of shorter series by various observers (over 200 cases, 70 per cent. being positive to the Dick reaction) agree in the main with American findings. Some 60 per cent. to 90 per cent. of cases of scarlet fever if tested during the first two or three days of the disease give a positive response. If tested two to five weeks after the onset of the disease some 70 per cent. to 90 per cent. of patients have developed a sufficient immunity to give a negative reaction to the Dick test (100 cases, 89 per cent. negative).

Schultz-Charlton Test.—Although the observations made in England up to the present are few in number, the results agree broadly with the American findings. The serum of a patient taken some weeks or more after the end of the disease will, when injected intradermally into the rash of a scarlet fever patient within 60 hours of its appearance, blanch an area of from 10 to 40 mm. ; this blanching appears in from 6 to 12 hours and lasts usually from 24 to 48 hours. We have immunised several horses with toxin and streptococci, and the serum of these horses when injected intradermally also causes the characteristic blanching in rashes due to scarlet fever but not in rashes due to other diseases. In England this blanching has been obtained in some 70 per cent. of over 100 cases tested.

Active Immunisation.—Apparently very little work has been done in England. We have injected many minimal skin doses into ourselves without producing any troublesome reaction.

Passive Immunisation.—Apparently 5 to 10 c.cm. of our horse serum injected intramuscularly will convert a " positive reactor " into a " negative " overnight. The serum should therefore efficiently protect children unwittingly exposed to infection.

Treatment.—The serum of several horses has been used therapeutically in some few dozen cases. The results can be characterised broadly as promising, and in some instances as very promising. The number is far too small to enable one to draw any satisfactory conclusions, but the evidence is such as to lead us to commence the immunisation of a larger number of horses so that sufficiently large supplies of serum will be available for a test carried on over many months.

Difficulties and Discrepancies.

The foregoing is a short account of what has been done. I should now like to deal with the difficulties and discrepancies.

Dick Test.—Here, as in all the work, we are greatly hampered since there is no means yet discovered of testing a given toxin in the laboratory. When we speak of the Schick test we can be certain that results obtained in half a dozen different countries are reasonably comparable, but with the Dick test this cannot be so readily assumed. There is little doubt that if an accurate method of titration were discovered it would be found that some of the Dick toxins in use for the test in various localities are two or more times the strength of those used elsewhere. We have tried all the obvious animals as well as white goats and kids and grey horses, cow's udder, abdomen of white sucking pig, the axilla of white sheep and lambs, but can find no practical method of testing in the laboratory. All toxins, therefore, must be tested on human beings. We have injected ourselves in the laboratory many times until we no longer give a satisfactory positive reaction. In America and France large numbers of people are available, but in England unfortunately they are not. How the difficulty is to be solved I do not know. It is a very serious one. Here, perhaps, I may be allowed to express the deep appreciation of myself and colleagues for the unlimited and prompt generosity of the whole of the American workers in putting at our disposal information and materials. We have tried to compare our toxins with those in use in America, but I know from American experience that a toxin may easily be labelled with half or double its real value when tested on a small number of people. So far as we can determine, the filtrates Dr. Okell has made are at least as strong and probably stronger than the average American toxins, and seem to cause fewer pseudo-reactions. At present we must go on collecting the observations made by a small number of medical officers and be prepared to alter our view about any given toxin whenever the evidence indicates. We have found recently an indication that a toxin with which Dr. Okell gets quite satisfactory positive reactions in the laboratory is giving a very low percentage of positive reactions in certain hospitals, mostly when testing patients in the first few days of scarlet fever, but also on patients not suffering from scarlet fever. It may be that transient positive reactions are being missed. It is puzzling that, during the same period, with the same toxin dilution from the same stock, satisfactory positive reactions are being got in other hospitals. It may be that it will be found necessary to use a given strength of toxin for testing healthy normal subjects, and a toxin several times as strong for testing scarlet fever patients in the first few days of the disease. Such a course would lead to great confusion and difficulty in keeping records, and one can only hope that it will not be found to be necessary. At present we have two dilutions being tested clinically, 1/6000 and 1/1000.

Schultz-Charlton Test.—We are naturally mainly interested in the blanching produced by the serum of immunised horses. In this test the American and Continental workers inject into the skin 0·5 to 1 c.cm. of serum. We are using 0·2 c.cm. The injection is much less troublesome for the patient and apparently gives satisfactory results, but we have not had enough experience to say which is the best quantity to use. Apparently some 75 or 80 per cent. of cases give an easily recognised blanching whether the serum be used undiluted or diluted even 200 to 500 times, but it is curious that in most if not all of the series done in England a small number of the patients suffering from typical scarlet fever have failed to show any blanching, though the serum has been injected intradermally in the very early stage of the disease. The most obvious suggestion is that there are two types of scarlet fever—A and B. It would be easy in a comparatively short time to confirm or refute this hypothesis. My own feeling is that it will not be confirmed, but evidence to-day is too slight to warrant anything more than a guess. We are collecting the streptococci from these " non-blanching " patients, and making toxin to see if one can demonstrate any difference from the ordinary toxin. If the result of the Dick and Schultz-Charlton test in these patients is known, and also the effect of their serum (taken when convalescent) in producing the blanching on other cases of scarlet fever, it will be easy in a relatively short time to decide the question.

Active Immunisation.—We have made toxin for active immunisation, and Dr. Okell has formalinised some toxin by the Glenny-Hopkins technique, but we have no group of people available on whom to test the immunising efficiency of these toxins. The results obtained recently in America already almost justify the conclusion that by testing and immunising the ward staffs in scarlet fever hospitals we can reduce attacks of scarlet fever amongst nursing staffs as satisfactorily as now, in many diphtheria wards, diphtheria amongst the nursing staff has been reduced almost to nothing. One point of importance here is that in the process of immunisation there is but little danger. In diphtheria a careless miscalculation has in rare cases caused diphtheritic paralysis or death, whereas the injection of very large doses of scarlet fever toxin into human patients has been followed by nothing more than a feverish attack lasting 24 to 72 hours with complete recovery thereafter. There need apparently be no hesitation in arranging for the immunisation of suitable people.

Treatment.—The results hitherto obtained are encouraging; it is too early to say more yet. But the great difficulty that faces us here is that of standardisation. There are two possible methods—the official U.S.A. method and the rash-blanching method.

Official U.S.A. Method.—In principle this method resembles the titration of diphtheria antitoxin by the intradermal method in guinea-pigs. Mixtures are made each containing a fixed dose of toxin and a dilution of the serum under test; the various mixtures are injected intradermically. If a flush—i.e., a positive reaction—occurs, obviously more serum must be used. This is continued until a balance is reached. So far as our experience of tests carried out on ourselves goes, the process is reasonably satisfactory and enables one to get an idea of the value of a serum. This value, of course, is much less accurate than in the case of diphtheria antitoxin, but still serves as a valuable measure of potency when arranging for the treatment of human beings. The only trouble is the obtaining of a supply of Dick positive people on whom to carry out the tests. The process of testing is practically painless and apparently free of danger, so that when suitable opportunity occurs there need be but little hesitation in carrying out the test, which is also a test of the patient's immunity to scarlet fever. The tendency of a number of tests would be to immunise the patient against scarlet fever after which, of course, he would be useless for this method of test. The second method is the one that is being used in England in which the serum is tested intradermally on scarlet fever patients before its therapeutic use. Into the rash is injected 0·2 c.cm. of dilutions of the serum proposed for use until the greatest dilution which will still produce blanching is found. We have compared our own horse serum with samples very kindly sent us from American colleagues; the serum in use in England will usually blanch in a dilution of 1/200 or even 1/500. The number of comparisons yet made is very small, but they tend to show that our serum has a value at least equal to the American serum. This method of testing appears to be more practicable under English conditions. Unfortunately, no one can as yet tell us definitely whether this method gives the same relative values as the official U.S.A. method. Until this problem of standardisation is solved no great improvement in the potency of the serum available can occur. We are using for the immunisation of horses the filtered toxin and the cocci themselves. We have applied the ordinary methods of concentration on a small scale to this serum, but we have not up to the present been able to form any idea whether a concentration of the scarlet fever antitoxin does result. I have little doubt that it does, for concentration has been used on a fairly large scale in America, but so far as our own work is concerned we are still without definite information.

Experience at a M.A.B. Hospital.

Dr. F. H. THOMSON (N.E. Hospital, Metropolitan Asylums Board) said that a number of attempts had been made to obtain a curative serum for scarlet fever. In 1896 Marmorek used an antistreptococcic serum, and later Aronson and Moser did the same. In 1897 Weissbecker used the blood serum of convalescent scarlet fever patients, but apparently in too small doses to be of value. About 1910 Reiss and Jungmann used convalescent scarlet fever serum in doses of from 40 to 100 c.cm., in a few cases with good results. In 1914 Zingher reported good results from the intramuscular injection of whole blood taken from convalescent scarlet fever patients. In 1923 Dr. Dochez attempted to immunise a horse by injecting agar into the cellular tissue of the neck, and when the agar had solidified, the hæmolytic streptococcus, thought to be the cause of scarlet fever, was introduced into the centre of the mass. Some six months later the serum of the horse was sent to Blake, who reported very favourably on its curative properties. However, Zingher, in a paper read before a joint meeting of the Association of Pathologists and Bacteriologists and the Association of Immunologists at Buffalo on April 17th, 1924, said that the results noted at the Willard Parker Hospital, New York, had been encouraging, but not as striking as those reported by Blake and his associates. Somewhat later the Dicks attempted to produce an antitoxic serum by immunising a horse with their toxin.

Antiscarlatinal serum as now prepared by the Department of Health, New York, as well as under the direction of Dr. Dochez had, Dr. Thomson was informed, been so successful that orders had been given to use it as a routine in all patients diagnosed as scarlet fever and admitted at the Willard Parker Hospital. Further, the medical staff and the research laboratory had been so convinced of the specificity of this mode of treatment, and its result in reducing the death-rate and diminishing the likelihood of complications, that they felt it no longer necessary to carry out control series of serum and non-serum cases. The more important benefits arising from the use of antiscarlatinal serum in the United States were the more rapid fall of the temperature, the statement of the sufferer that he so quickly feels his condition to be improved, and the more rapid fading of the rash.

It was well to note, Dr. Thomson said, that scarlet fever in the United States had recently been, and no doubt was now, a more fatal disease than in this country. As an indication of this, he gave the total number of cases admitted, and the death-rates during the five years 1919 to 1923 at the Willard Parker Hospital, and at the North-Eastern Hospital of the Metropolitan Asylums Board.

Year.	Willard Parker Hospital.		North-Eastern Hospital.	
	No. of cases.	Death-rate per cent.	No. of cases.	Death-rate per cent.
1919	526	5·9	1404	0·98
1920	614	12·0	2955	0·87
1921	1316	8·4	3300	0·94
1922	895	8·2	1536	1·95
1923	589	4·6	1098	1·8

In February last, through the kindness of Dr. R. A. O'Brien and later of Dr. A. T. MacConkey, he was enabled to commence the treatment of scarlet fever with sera prepared by them. The difficulty was to find suitable cases on which to test the curative value of the serum, and most of the cases selected could not be called other than mild attacks, though all were not so. Thus from the point of view of testing the value of the serum he was at a definite disadvantage when compared with New York. Again, the paucity of cases suitable for this treatment at his hospital rendered it impracticable to compare the results with a series of non-serum cases. This form of control, however, with scarlet fever so mild as it is, would have been of negligible value. With regard to the statement that the patient felt distinctly better after the administration of the serum Dr. Thomson had found difficulty in getting at the facts, for the average patient on coming into hospital was placed in conditions of comfort which did not exist at his home, and this helped him to regard his condition as considerably improved. Again, most of the sufferers were young children who did not necessarily give expression to facts, and who were influenced by the customary suggestion of the nurse to say "I am better, thank you, doctor." On the other hand, one of the children treated insisted that he was no better for some days, but this was obviously untrue.

Observations on Thirty-seven Cases.

"Up to the 6th of May," said Dr. Thomson, "I had treated 37 cases. These were the cases admitted with more pronounced rashes, and in all the serum was administered intramuscularly. At the commencement I gave 20 c.cm. until Dr. A. T. MacConkey kindly told me that Dr. Dochez gave 40 c.cm., when I adopted the latter dosage. Of the 37 cases 13 were on the first day of the rash, 23 on the second, and 1 on the third. In drawing deductions I find it safer to date from the commencement of the rash, since that can be more accurately ascertained than the date of the onset of the disease, which is often unreliable.

"When the antiscarlatinal serum was given on the first day of the rash its average duration was actually less than in those treated on the second day. Some rashes, whether treated on the first or second day, seemed to be affected but little if at all, one or two faded unduly rapidly, and several showed a lessening of rash intensity in about 24 hours from the time of the injection of the serum. However, even when the rash intensity was lessened it did not usually fade rapidly afterwards. Indeed, in one apparently severe case the rash lasted a further six days. The effect of the treatment on the rash varied greatly, just as I have found in the intradermal extinction test. I have had one or two cases of clinical scarlet fever which failed to give a local blanching reaction on intradermal injection of a serum which reacted well in others, and one of them might be described as a classical case of scarlet fever.

"The effect of the serum treatment on the temperature of the patient in the type of scarlet fever we are dealing with was, on the average, not very marked. After studying the temperatures of a considerable number of non-serum treated cases, I am disposed to think that the antiscarlatinal serum treatment frequently results in a slightly more rapid fall and that the temperature falls to normal somewhat earlier.

"A few adult and adolescent patients have positively assured me that they felt distinctly improved in about 24 hours after the administration of the serum. There were a few cases of ulceration of the tonsils and nasal discharge amongst the cases treated, and one of ulceration of the soft palate, and these seemed to follow a more benign course than I would have expected, but they were too few in number to draw any conclusion from. It is worthy of note that in a high proportion joint pains followed the use of the serum. Perhaps this might be expected since rheumatism, though not a frequent complication of late years, was common when the disease was more severe.

"In one case I was much impressed, for when I first saw her I considered she was at the beginning of a severe attack; she had a deeply tinted rash and considerable faucial œdema. She had a toxic appearance and said she felt very ill. In about 24 hours after treatment she had lost her toxic appearance, said she was very much better, also looked so, and her temperature had fallen four degrées. Three days later she developed ulceration of the tonsils accompanied by nasal discharge which lasted for a few days. Her rash persisted for seven days."

He was well aware, said Dr. Thomson, that deductions could not be drawn from a few cases, and that an apparently severe case of scarlet fever might unaided rapidly improve, but he was favourably impressed with the very little he had seen of the antiscarlatinal serum treatment. One or two patients in whom improvement might have been expected from this treatment did not bear out the expectation. The same serum when injected intradermally often produced differing local blanching reactions and occasionally failed altogether. Hence the need of more information and of an answer to the question: Are we dealing with more than one type of scarlet fever and perhaps with mixed infection as well?

Discussion.

Dr. S. M. Copeman, F.R.S., said that as a member of the Scarlet Fever Committee of the Ministry of Health he had visited New York and had been exceedingly impressed. Dr. Zingher had inoculated a large number of cases prior to his arrival in order that he might have an opportunity of seeing every variety of the Dick test. But there was a vast amount of work still to be done, for the Dick test in certain respects was quite unlike the similar tests in diphtheria. It was not yet absolutely certain what was the organism concerned in scarlet fever, and no method had been found to carry out tests on laboratory animals. Some time ago it was decided by the Ministry of Health to investigate on a large scale; amongst other centres, Liverpool and Manchester promised full coördination with the Ministry's Pathological Laboratory. A meeting of all concerned had taken place at the Government Laboratories, and a considerable amount of work had been carried out on the bacteriological side, and not in relation to the operation of the Dick test or the possibility of active treatment. He was greatly interested in the protection of nurses and residents in infectious disease hospitals, and with regard to diphtheria he had always urged that nurses should not be allowed to go on duty in the wards until Schick tested and, if positive, immunised. He hoped it would be possible before long to issue a definite suggestion to that end, and also in the same way with scarlet fever.

Dr. C. C. Okell (Wellcome Physiological Research Laboratories) said that with regard to the standardisation of the Dick toxin there was great difficulty in matching two toxins. They had made filtrates not only from the Dochez strain but from the Dick strain, and from one or two strains of their own, but outside work had been restricted to the Dochez toxin. The toxins were not all of the same strength, but could be made so by suitable dilution, and it could probably be claimed that the Dick tests being carried out in the several countries were the same. Doubtless everybody wanted to know what was the correct dose—the dose that would divide patients accurately into two groups, those who would get scarlet fever and those who would not. That point had not yet been settled, and only much experience would provide the answer. Evidence, of course, was rapidly accumulating which showed that the Dick negative did not take scarlet fever, but light still had to be thrown on the meaning of the partial reactions, and whether or not the people who gave them were susceptible to scarlet fever. Dr. Okell instanced several specific cases of positive reactions, including that of a nurse, the only Dick positive in a group, who before she could be got out of the ward developed scarlet fever. One thing might help to clear up certain difficulties—viz., the study of the disease with a serial Dick test day after day during its course. Such a test done in parallel with the Schultz-Charlton would give valuable information.

Dr. D. S. Sutherland (Monsall Hospital, Manchester) stated that they had done 420 Dick tests in the first three months of the year in 127 cases in successive days, taking groups of cases on the first day of the disease, the second, third, fourth, and so on, and had found that the percentage of positives was considerable in the first two weeks of the disease, and that thereafter there was a gradual decrease. After the twenty-eighth day no positive results whatever were obtained. It was found that the reactions were rather subtle things, and a sharp look-out had to be kept for the tests. Dr. Sutherland gave details of an interesting observation. In a large ward 50 cases of diphtheria had been exposed to a septic scarlet fever case before it was removed. The whole ward had been Dick tested, and 15 patients gave a positive result, and it was a notable fact that the scarlet fever picked out throughout the ward the Dick positive cases, including the doctor in charge. In conclusion, Dr. Sutherland said that they had recently been using convalescent serum in septic cases with very beneficial results.

Dr. J. C. Blake (N.E. Hospital, M.A.B.), speaking of the Schultz-Charlton test, remarked that the number of cases done had been small owing to the few admissions and the mildness of the rash. Owing to the difficulty in reading the result, it had only been employed where the rash was well marked or likely to develop. In 29 cases injected, 7 showed no blanching. In each case several dilutions, varying from 1–10 to 1–500, were used. One case only showed blanching with a 1–500 dilution, 6 with 1–300, and the remainder all showed blanching with dilutions from 1–10 to 1–300. Using 1–10 the blanching persisted right up to the time of the rash, and even after the rash had faded. Of the 7 cases that had shown no reaction, 3 had good rashes which faded within 24 hours of admission, and 2 also had good rashes which faded on the third day after admission. The average time for blanching to occur was 14 hours 20 minutes, the shortest period being 3 hours 20 minutes, and the longest 46 hours 20 minutes.

Dr. W. **Mair** (Research Pathologist, M.A.B.) observed that it was curious that serum which blanched the majority of the rashes failed to blanch the individual rash. There was unfortunately no really satisfactory method of measuring either the toxin or the antitoxin. Another point of interest was the question of the period at which the Dick test became negative.

Dr. W. A. **Lethem** said that at Liverpool he had found his negatives increase very largely as the period of convalescence went on, but had nevertheless obtained a small group of Dick positives where he would have expected Dick negatives. This he had attributed to a temporary lack of immunity at that period.

The **Chairman** said that at the North-Western Hospital not very much had been done, but so far as they had gone the results of the Dick test did not agree at all with one another, and apparently a good deal depended upon the toxin used. One of 1–6000 at the North-Western Hospital failed almost completely, though he understood it had been successful elsewhere. He had been glad to note the reserved tone of the discussion, for after all they were not so sure of their ground as with the Schick test. A question had been raised as to the number of nurses in the Board's institutions who had caught scarlet fever. Up to 1914 the Metropolitan Asylums Board had published the number of cases of all infectious diseases contracted by their staff, and from those figures it would be easy to calculate the incidence up to that date. Since that year it was doubtful if the information was available. Records were, however, kept at the several hospitals, and it would be possible to obtain the data if necessary. The cases of scarlet fever seen nowadays were so mild that it was better to leave them alone, and that was one of the reasons why he had not himself yet tried the methods under discussion. He had not had for some months a really serious case of scarlet fever. One also had to remember that in the past sera had been tried with varying results. In typhoid fever, for instance, some curious results had been obtained in the use of serum.

Reply.

Dr. **O'Brien** agreed that most scarlet fever cases that occurred in London were very mild, and that one would hesitate to add in any way to a patient's discomfort in such circumstances. At the same time it would be well to bear in mind the possibility of complications being reduced in severity by the use of the system. In concluding, Dr. O'Brien gave particulars of two interesting instances. In the first, eight cases had been sent into hospital diagnosed as scarlet fever. They did not appear to be scarlet fever to the admitting physician, who had them Dick tested. Negative results were obtained in each case; they were put in a scarlet fever ward, and did not get the disease. In the other instance, six positives were obtained and up to that day four had caught scarlet fever.

Dr. **Thomson** said that, as a matter of fact, none of the cases in his hospital had been severe, but that was not the point. Scarlet fever varied in severity over long periods, and not knowing when it would again become serious they should be prepared to deal with it.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

A meeting of this Section was held on June 6th, Dr. **Kerr Love**, the President, being in the chair.

Artificial Aids to Hearing.

Mr. J. F. **O'Malley**, in opening this discussion, said the instruments which had been introduced to aid the deaf could be classified into the mechanical and the electrical. Among the former were the ordinary speaking tube for carrying sound to the listening ear, sound collectors on the same principle as sea shells, some of which were worn as artificial auricles, banjoes, trumpets, &c., either straight or coiled. The electrical aids were of two types: the ordinary one was the battery transmitter and receiver, and the regulator, the effect of the instrument being capable of intensification by moving an arm on a rheostat. The receiver was supposed to act by air conduction and bone conduction, but one form acted by bone conduction only, and one make of instrument conducted sound by bone conduction only, being placed against the mastoid. An apparatus had also been devised for lip-reading. By combinations of the various devices it was possible, he said, to make 90 different types of instrument. For moderate degrees of deafness he considered the mechanical aids were the most valuable and the least troublesome; while for the more intense degrees of the disability the electrical were the better. Illustrations of typical examples were projected on to the screen and demonstrated by the speaker.

Mr. W. M. **Mollison** said that he had recommended these aids very little; he usually sent people requiring them to an electrical expert. His general experience was that patients with high degrees of middle-ear deafness and otosclerosis were almost always helped by some form of electrical instrument. Cases of internal-ear deafness and short bone conduction were seldom helped by them, though they were sometimes. A useful rough indication in advising patients what to get was to ascertain, by means of the monochord, the highest pitch they could discern. Many could not hear the monochord at 30 to 40 cm., but yet could hear it well through the bone, and these would practically all get some benefit from an instrument. Small cornets worn under the hair were very useful.

Dr. W. H. **Kelson** asked whether members had any experience of cases of deafness who were made worse by the continual use of these instruments. He had heard such complaints, which included headache. Possibly over-use produced an inflamed organ.

Mr. **Herbert Tilley** spoke of the great help in hearing sometimes given when there was a large perforation of the drum by placing in the ear a small pledget of wool soaked in liquid paraffin. He did not advise a gutta-percha disc, as it was liable to become foul and septic. The wool plug could be used gradually at first until the patient was accustomed to it.

Mr. A. R. **Tweedie** said Bárány considered that the sound proceeded through the foramen ovale and then through the helicotrema and the foramen rotundum, and that hearing was due to excursions of the round window with excursions of the oval window. This pre-supposed that there must be an exposed and a tolerant middle ear. If a paraffin or mercury droplet were run into the external auditory meatus and the head tilted backwards to enable the droplet to pass into the fossa rotunda, so that it took the place of the normal droplet of mucus, it ensured the sound waves going only one way, the correct way.

The **President** said the chronic non-suppurative conditions of the middle ear constituted one of the reproaches to otology. Great advances in the surgery of the ear had been made in the last 30 years, but practically none in this particular part of the field. Electrical aids to hearing were far too expensive for most people, and often their effect was uncertain. Mere increase of the loudness of the voice as heard was not sufficient, as the voice was compound, and no instrument intensified it over its whole range. Success had been partially attained by the Western Electrical Company, of New York, who had elaborated an apparatus on the principle of the Ordeon amplifier. In middle-ear cases the difficulty was to increase the value of the low tones without increasing the high tones; and in the internal-ear type of deafness the trouble was to increase the high tones without increasing the low ones. The acousticon had been tested for some days on 60 or 70 Glasgow semi-deaf school-children, and the results were disappointing. He agreed with Mr. O'Malley that there was nothing at present more efficient than the hearing tube. He thought the Section should do all possible to protect inexperienced patients against the abuse which existed in connexion with foisting costly instruments for which much was claimed. Members should lay down the condition that patients should not be asked to buy these instruments without a thorough test being carried out. He thought that occasionally such a plug as Mr. Tilley mentioned had re-established discharge in a dry ear by acting as an irritant foreign body.

Mr. Sydney Scott referred to a committee which was appointed many years ago to investigate aids to hearing, and said that committee could not then examine the Marconi instrument, though some members had done so since. The condition known as otosclerosis was usually benefited by electrical aid. Patients with senile deafness, who could hear low tones but could not analyse them well, and had lost very high tone perception, heard better with a plain speaking tube. He had never yet seen a child whose middle-ear deafness was improved by the use of the acousticon. He agreed that a pledget of paraffin-soaked wool inserted in the ear was very liable to set up suppuration, and he had warned patients of that risk. This pledget could be used in the case of very relaxed drums, in which no perforation was present at all.

Sir James Dundas-Grant said that if possible the mechanical devices should be used rather than the electrical, though in the matter of elegance the latter deserved much consideration. The banjo-shaped instrument was the one he found most acceptable as a rule. Some tubes for the purpose were of uniform bore, but they should always be of a gradual taper. In some continental statistics dealing with 368 patients, 44 per cent. derived most help from ear-trumpets and 45 per cent. from electrical apparatus. Only 19 per cent. of patients with internal ear deafness liked electrical apparatus. The cotton-wool drum, which was the idea of Mr. Yearsley, was an invaluable aid. In the intervals between wearing the drum he recommended the application of a little dilute alcohol as a precaution against any return of the discharge.

Prof. Burger, of Amsterdam, said that in the schools for the semi-deaf in that city a valuable instrument was a megaphone with small modifications.

Mr. F. J. Cleminson said he was largely in agreement with Mr. O'Malley on this subject. Patients who had senile deafness found difficulty in separating words heard, and the ordinary apparatus did not help them in this respect. But an instrument projected by Myrocwitz largely succeeded in separating the words without unduly magnifying their intensity. The instrument could be held in the hand, it was small, and certainly clarified speech. He had used an artificial drum in one case only, and it was a very great success; it had been worn daily for nearly five years, and there had been no suppuration.

Dr. J. S. Fraser said his experience was that the long black hearing tubes were the best form of apparatus available for very bad cases of nerve deafness, though he doubted whether they gave much more benefit than that obtained from placing the curved hand behind the ear. In otosclerosis the auricles made by Hawksley were very good, also in cases with a cicatrised tympanum. Most makers refused to allow prospective purchasers a fortnight's trial, which was a hardship on the patient, as the instrument might not suit his case.

Mr. H. J. Banks-Davis spoke of a patient who derived great benefit from placing a small piece of bacon rind in his ear, the amount of fat on it apparently affording the needed consistency. He heard so well with this, as the speaker could testify, that his deafness did not worry him.

Mr. R. Graham Brown (Queensland) could not say much in favour of the acousticon. His custom with patients was to tell them to go to the instrument maker and try apparatus for themselves, and if a fortnight's trial gave satisfaction they could buy the instrument, but he would not himself take responsibility in regard to them.

Mr. Lawson Whale said he found that the people who were made worse by the use of electrical aids were those who had tinnitus, and this was aggravated by the instrument. All makers should be compelled to allow trial before purchase.

Mr. Scott Stevenson said some of the machines on the market were bad from the standpoint of physics. Bell discovered that the vibrating diaphragm was the best means of conveying the human voice, and the speaker thought a good means of aiding these patients would be by an adaptation of the microphone, which was a very primitive instrument in the light of the great advances in physics generally in the last half century. He was in the habit of telling patients that they were not likely to get much more benefit from anything than from the ordinary trumpet-shaped tube.

Mr. R. T. Worthington said all were agreed that mechanical aids were the most effective, but he thought research would produce an electrical apparatus superior to any other. He had a deaf patient who was very anxious to use the wireless apparatus, and she said the Brown was far the best, and it gave less distortion of upper notes than any other.

Several cases were shown and discussed, and Mr. A. Cheatle and Mr. V. E. Negus demonstrated some casts of labyrinths. The debate on drainage of brain abscess was adjourned to the autumn session.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held in the Hall of the British Medical Association recently opened at 6, Drumsheugh-gardens, on June 3rd. Sir David Wallace, the President, in opening the meeting, congratulated the Association on their acquisition of premises in Edinburgh.

Mr. David Lees read a communication, with six illustrative cases, on

Treatment of Syphilis of the Central Nervous System by Tryparsamide.

It was pointed out that tryparsamide did not contain so much arsenic as the arsenobenzols, but possessed more power to penetrate the tissues of the central nervous system; it also possessed a powerful stimulative effect on animal economy and resistance, together with a moderate degree of treponemacidal action. Eighteen patients had been treated, all of whom suffered from syphilis of the central nervous system to a marked degree and who had previously been under treatment with no great improvement. Patients should be prepared as for other arsenical preparations and an intravenous injection of the filtered drug carried out; 2 g. were given at the first injection, thereafter 3 g. weekly to a total of 24 g. A month's rest was then allowed, after which the drug might be re-exhibited if necessary. The use of the drug was contra-indicated if there was optic atrophy or any lesion of the optic tract, and for this reason the eyes should be carefully examined beforehand. Adjuvant treatment of "914," bismuth, mercury, and potassium iodide might be carried out if necessary. The drug with few exceptions was tolerated well. Weight was well maintained but not increased. In many cases there was marked improvement in general health, the patients were able to carry on work (one was able to resume work from which he had been absent for some time), cerebration improved, and the power of application to work was considerably better than previously. In the cerebro-spinal fluid the cell count decreased in all cases with a decrease of globulin and a diminution, even a disappearance, of the positive Wassermann reaction; the goldsol test of Lange showed marked improvement in every case. The Wassermann reaction of the blood was not materially altered. The great point in the superiority of tryparsamide to any other method was the ease of administration without any discomfort to the patient. From the fact that it did not affect the blood Wassermann to any great extent, it would appear advisable to exhibit adjuvant therapy with salvarsan and bismuth at the same time. Tables were shown demonstrating the diminution of the cerebro-spinal fluid, Wassermann reaction, cell count, globulin, and goldsol curve, after treatment by tryparsamide, this not having occurred previously with other drugs.

Auto-Intoxication and the Nervous System.

Dr. CHALMERS WATSON read a paper, illustrated by two cases, on the rôle of auto-intoxication or auto-infection in the ætiology of disease of the higher and lower nervous system. He laid stress on the limitations in the treatment of nervous disease. Diseases of the nervous system, he said, were divided into a watertight compartment and held separate from medicine in general, consequently the outlook was limited and progress would not be made till the matter was considered on broader and sounder lines.

Reviews and Notices of Books.

PHYSIQUE AND CHARACTER.

By E. KRETSCHMER. Translated from the second revised and enlarged edition, by W. J. H. SPROTT, B.A. London: Kegan Paul. 1925. Illustrated. Pp. 266. 15s.

THE conception of the correlation of bodily structure with mental character is not new in the history of medical science. The early enterprises of Gall in this direction were confined to the variations in size and shape of the skull, and gave rise to the practice of phrenology, but with the negation of any correspondence between the external configuration of the head with the pattern of cerebral convolution the whole schema fell into discredit. Another notable attempt was that of Lombroso, who first formulated the conception of "stigmata of degeneration," which still has a certain validity inasmuch as mental inefficiency is a manifestation of degeneracy showing itself both psychologically and physically. Recent investigations have shown that the visceral organs, particularly the endocrine glands, in their association with the autonomic nervous system, play an important part in psychological function. Consequently the psychiatrist and the psychologist are once more paying considerable attention to physical structure in relation to mental function.

The valuable portion of the book under review consists of the observations made by the author on the correlations between certain physical types and the two general mental dispositions towards a schizophrenic or a cyclothymic reaction. As is stated in the preface, a certain amount of confirmation has been derived from other workers, and providing that the cautious and critical tenor of the book is reflected in the mind of the reader, the results may prove of considerable value from the anthropological and the biological standpoints. A careful and comprehensive scheme of examination was applied, measurements of the relative proportions of the skull, facies, limbs, and trunk playing a large part in the differentiation of the types. Attention is given to any indication afforded by the condition of the skin or any organ which can be examined from the surface of the body. The age of onset of certain functional activities, such as the menses, is noted, and the time of deposition of fat. The general distribution of hair and of the subcuticular fat is mapped out. Side by side with this physical investigation are the psychological description of the subject and of any factors in the ascertainable heredity which showed a bearing on the problem.

Some 260 cases were dealt with in this way, and there emerged three main types of physique which the author terms the asthenic, athletic, and pyknic respectively. The asthenic individual is "the lean man with a skin poor in secretion and blood, narrow shoulders from which hang lean arms with thin muscles and delicately-boned hands; a long narrow flat chest, a thin stomach devoid of fat, and lower limbs which are just like the upper in character. In the average values the weight falls behind the height, and the chest measurement behind that of the hips." The athletic type is the middle-sized man with wide projecting shoulders, a well-developed chest, firm abdomen, and a trunk tapering in the lower region. The bony skeleton is heavy and the musculature is hypertrophied. This type has certain relations with the endocrine abnormalities such as acromegaly and some dysgenitalic states. The pyknic type is characterised by the pronounced peripheral development of the body cavities, the head, chest, and abdomen, and a tendency to the distribution of fat around the trunk. In distinctive cases the appearance is that of an individual of middle height, rounded figure, with a soft round face on a short massive neck; the fat abdomen protrudes from the deep-vaulted chest which broadens out towards the lower part of the body. In addition to these three main types there are several others of a mixed and dysplastic variety which occupy extreme and intermediate positions. The author finds that there is "a clear biological affinity between the psychic disposition of the manic-depressive and the pyknic body type, and between the psychic disposition of the schizophrenic and the bodily characteristics of the asthenic, athletic, and certain dysplastic types." The description of the types is full and distinctive, and the question of mixed constitution, psychological and physical, resulting from variants in the hereditary family groupings, is dealt with at considerable length. The second part of the book, dealing with the cycloid and schizoid temperaments and their incidence among average individuals and in men of genius, is less convincing.

The arrangement is good, and the printing clear. On page 126 in paragraph 3 "liable" should read "labile." It is a pity that the translator should have aimed at such a literal standard in his work, as the text does not provide easy reading. Further, the translator shows an occasional lack of familiarity with the use of technical expression—e.g., the terms "idiocy" and "imbecility," which connote congenital mental defect and should not be employed in describing demented states resulting from the psychotic disturbances of adult life.

THE STORY OF ANZAC.

Official History of Australia in the War of 1914–18. Vol. II.: *The Story of Anzac.* By C. E. W. BEAN. London: Australia House, Australian Book Company; Australia: Angus and Robertson, Sydney. 1924. Pp. 700. 28s.

A THRILLING story of the heroism and persistence with which Australia and New Zealand threw their young armies into a great adventure, which achieved much but failed of complete success, is here told; the failure is now known to have occurred through the inexperience in the directors, and the cross-currents of policy which have always weakened coalitions. The volume is little directly concerned with the health problems of the expedition, to be dealt with later in an official medical history now being written for Australia by Colonel A. G. Butler. The health of the troops, it is here stated, was good until flies notably increased in May; then diarrhœa became frequent and dysentery began to cause anxiety. The food supplied comes in for criticism, and though some South African veterans declared it luxurious, there were many observers who thought it had affected the health of the army "more than any other factor, except the bullets and shells of the enemy" (p. 365). The editor's footnote adds: "It is doubtful if this opinion is sustained by the evidence," but he closes his chapter, "The fact remained that, while the soldier on the veldt 15 years before had kept fit on his half-ration, the man on Gallipoli with his whole ration fell sick." But how many other differences there were between service in Gallipoli and South Africa! At Gallipoli, as mentioned in this book, the whole area occupied by the armies was very small, scarcely extending four miles from the beach, and was always overcrowded; the soldier was rarely safe from bombardment, not even when bathing in the sea; heat, dirt, smell, diarrhœa, flies, lice, and fleas were his daily portion; he had hardly enough water to drink, let alone to wash himself or his clothes; at night to avoid shell-fire he must often sleep in a crowded, ill-ventilated dug-out; casualties were tremendous, the personal outlook sombre; there were no periods of rest, no variety, even the landscape was always the same, dominated by "the big, whale-like shape of Sari Bair" or other ridge of horrid memory; he could neither buy nor "find" any different food. So it was no wonder that (p. 801) in September Colonel Sir James Purves-Stewart found half the old soldiers in the front line had weak and rapid heart action, and recommended the troops should be rested. This was difficult to manage since the reserves were so few. Dental decay was another problem; in time dentists were acquired from Australia. The gradual development of the medical organisation of the Australian force is well described.

This book suitably depicts a wonderful enterprise.

PÆDIATRICS.

Clinique Médicale des Enfants: Affections de l'Appareil Circulatoire. By P. NOBÉCOURT, Professeur de Clinique Médicale des Enfants á la Faculté de Médecine de Paris. Paris: Masson et Cie. 1925. Pp. 371. Fr.25.

IN this second volume of Prof. Nobécourt's Clinique Médicale, dealing with cardio-vascular diseases of children, the teaching of one of the highest authorities on the subject is presented in a form which is both original and attractive. Each chapter consists of a detailed account of one or more patients, followed by a dissertation on the conditions depicted in it. A large number of different combinations of cardiac lesions are dealt with in this way, which renders a certain amount of repetition inevitable, but this is more than compensated by the vivid presentation of clinical pictures which each of these lectures conveys. The cases are illustrated by numerous orthodiagrams and charts.

The lucid and readable style of the book, will place it among the most important works in the literature of children's diseases.

FORENSIC MEDICINE.

By HARVEY LITTLEJOHN, M.B., F.R.C.S. Edin., F.R.S.E., Regius Professor of Forensic Medicine, University of Edinburgh. London: J. and A. Churchill. 1925. Illustrated by photographs and descriptive cases. Pp. 285. 15*s.*

To read this volume is to pay a visit to a well-catalogued medico-legal museum; its principal feature consists of 183 most admirable photographs of post-mortem and certain other conditions, including drowning, strangulation, burns, wounds, and infanticide. This way of demonstrating forensic medicine is a new departure, and, since there is a full description appended to every photograph, it will be found most helpful by students. Moreover, such a collection of representative and first-rate specimens must, we think, be of the utmost interest to the medico-legal expert. The volume will be appreciated by the candidate for examination in forensic medicine; it should play a part in his reading, corresponding to illustrations of dissections in anatomy and surgery. It is indeed remarkable that no such compilation has been made before in forensic medicine, for concrete examples render learning more real and knowledge more permanent.

The book is not intended to replace an ordinary text-book, since it is stated in the preface that those aspects of the subject which are not adapted to illustration have been deliberately omitted. In so far as a practitioner makes a special study of the medico-legal aspect of his many-sided practice, this volume will be of value to him, while every district or police medical officer would be the better equipped by its possession.

AN INTRODUCTION TO SCHOOL MEDICINE.

By H. LESLIE CRONK, M.A., M.D., D.P.H. Cantab., Assistant County Medical Officer, Lancashire. London: H. K. Lewis and Co., Ltd. 1925. Pp. 236. 7*s.* 6*d.*

"THE school is the link between the intimate sheltered life in the home and the strenuous fight of adult working years; in like measure the functions of the school medical officer lie midway between the personal attentions of the family doctor and the more general and impersonal activities of the medical officer of health." This quotation well represents Dr. Cronk's level-headed views. The school medical officer is an important link in the chain of health which commences with the antenatal clinic and works up through the infant and child welfare centre to the school clinic. He is, moreover, dealing not with patients who are likely to be seriously ailing, but with presumably healthy children who may have minor defects which it is his duty to detect and remedy early. While diseases of children on the one hand and matters of school hygiene on the other are well treated in many text-books, there was still room for an account of the minor departures from health of children attending school, and Dr. Cronk has taken up this subject and dealt with it very effectively. He admits that his main business has been to assemble the material on this subject which is scattered for the most part through many text-books and journals. So the book contains no startling theories or long records of personal experience, but it effectively covers the ground indicated by its title in small space.

BACTERIOLOGY.

Bacteria in Relation to Man. By JEAN BROADHURST, Ph.D., Associate Professor of Biology, Teachers' College, Columbia University. London: J. B. Lippincott Company. 1925. With 146 figures. Pp. 306. 12*s.* 6*d.*

AN excellent, interesting, and cheap lecture outline and practical class-book on bacteriology taken in a broad way. It is intended to form the first part of a book of which the author's "How We Resist Disease," noticed in THE LANCET,[1] is the second volume. It is certainly very good, and teachers of bacteriology to medical students would do well to go through it and resurvey their own courses. Some of the vivid liveliness of the present, and more of the respect for the past history of the subject might be transplanted with advantage. For whom the book is intended in Columbia University is not very clear. It is one of a series of "Nursing Manuals," and that it is framed for those with a limited scientific training is suggested by finding such words as "cubic centimeter" defined in the glossary at the end. How a nursing course could properly include such a book is beyond understanding, and one suspects that it is one of many attempts to do what mankind has ever tried—find a royal road to learning. But for whoever it has been written, it will prove a very good book for those who have been adequately prepared to use it.

---

[1] THE LANCET, 1923, ii., 20.

Text-Book for Nurses.

Anatomy, Physiology, Surgery, and Medicine. Third edition. By E. W. HEY GROVES, M.D., B.Sc., M.S., F.R.C.S.; and the late J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxf., M.R.C.P. Lond. The Medical Section revised by J. A. NIXON, C.M.G., M.D. Cantab., F.R.C.P. Lond. London: Humphrey Milford, Oxford University Press. 1925. Pp. 645. 20*s.*

SINCE its first appearance in 1912 "Groves and Brickdale" has been recognised as a valuable text-book for nurses. The third edition does not differ greatly from the original issue. The object of the authors has been to present the elements of anatomy, physiology, surgery, and medicine in a simple yet accurate manner, and in the preparation of this new edition the text shows signs of careful revision to secure this end. In the medical section some of the chapters have been rewritten and a new chapter on Hygiene has been added. This contains a short account of such subjects as water-supply, ventilation, refuse disposal, personal hygiene, disinfection, heating and lighting, all subjects with which the modern nurse must be to a certain extent familiar, for the modern patient has often more than a smattering of knowledge on these public health questions.

A close study of this book should enable any nurse to grapple successfully with the various theoretical examinations with which she is confronted.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. March and April, 1925.—In the March issue Dr. H. W. Haggard discusses the toxicology of hydrogen sulphide, which he concludes may produce fatal poisoning with a concentration of 0·2 per cent. of the atmosphere. Below 0·1 per cent. respiration is little affected. The heart continues to beat after respiration has failed; therefore artificial respiration as a method of resuscitation is important. The gas is an irritant to the eyes as well as being toxic. When inhaled in small amounts, hydrogen sulphide is rapidly oxidised in the body, when its toxicity is neutralised.—Inhalation as a path by which industrial poisons enter the body is dealt with by Prof. L. Preti, who points out that the respiratory apparatus is a path of entry for most industrial poisons whether in the form of gas, fumes, vapours, or dust. Neither gases nor fumes produces pulmonary lesions different from those of ordinary inflammatory processes. Certain dusts lead to pneumonoconiosis; while toxic dusts, such as those of lead, cause their specific form of poisoning. The writer considers compulsory insurance against occupational diseases a valuable way of bringing about their prevention.——In the April issue the subject of punctate basophilia in lead workers receives attention from Dr. A. Sellers, who has conducted blood examinations of a number of men exposed to lead absorption. He considers that the presence of punctate basophilia is an extremely delicate method of detecting lead absorption, and that its degree affords indication of the amount of absorption taking place, even though it cannot distinguish between absorption and clinical symptoms of poisoning.—H. Green describes methods for photographing and measuring fine particles, such as are liable to be inhaled in industry. He points out the difficulties associated with the work. His paper is one which must be of value to photomicroscopists.—The third of a series of articles dealing with the laundry trade is contributed by Miss M. Smith, who discusses atmospheric conditions as found by her. She concludes that variations in output are not unconnected with the problem of ventilation, and points out that even where temperature cannot be reduced owing to machines, such as calenders being hot, still conditions can be mitigated by keeping the air moving. The evidence she quotes supports the need for keeping laundries cool by such things as lagging steam pipes and covering lids of presses with asbestos.—The last article, by Prof. E. L. Collis and Dr. H. M. Vernon, reports upon a comparison of old and new processes in the tinplate industry. A new labour-saving device, which combines several processes previously carried out by hand, is described. This machine exposes the workers to less radiant heat, to lower air temperature, to more rapid air current, and less fumes and dust. The men employed under these conditions were found to experience better health and to possess greater earning capacity.

THE price of Mr. H. W. S. Wright's "The Conquest of Cancer," reviewed last week, is 2*s.* 6*d.* and not as stated.

MINISTERIAL DECISIONS ON THE CONDUCT OF INSURANCE PRACTICE.

REPORTS OF SIX INQUIRY COMMITTEES.

WE print below summaries of the findings of six Inquiry Committees appointed by the Minister of Health during the past six months to investigate representations that the continuance on the panel of an insurance doctor would be prejudicial to the efficiency of the medical service of insured persons. Except where otherwise stated, the complainant was an Insurance Committee. Those facts only are summarised which the Inquiry Committee found to be proved by the evidence submitted to them. The decision given by the Minister after considering the Committee's report is appended to each case. It will be observed that in three cases the Minister, although deciding that the doctor's name should not be removed from the Medical List, imposed a pecuniary penalty. The justice of this policy, more especially in connexion with Cases 4 and 5, has been called into question by some representative members of the profession.

(1) *Failure to Keep Adequate Records, or to Supply R.M.O. or Insurance Committee with Information.*

In this case the Minister himself initiated the appointment of the Inquiry Committee.

(*a*) Dr. A. B. practised in an industrial area and had at the material time 317 insured persons on his list. On various dates he received from the R.M.O. 17 forms R.M.2[1] in respect of insured persons to whom he had issued certificates of incapacity, and subsequently R.M.O. sent him reminders. As the doctor failed to return the forms, the divisional medical officer wrote special letters in seven of the cases, calling the doctor's attention to his failure to carry out his obligations under his terms of service. Subsequently the divisional medical officer visited Dr. A. B., who then admitted receiving the forms and reminders and promised to comply with the regulations in future. None of the forms was in fact returned. A year later the R.M.O. visited the doctor and pressed for the return of two of the forms which were specially needed. The doctor promised to return them, but did not. Since the beginning of 1921 Dr. A. B. had returned to the R.M.O. only three out of 20 forms R.M.2 which had been sent to him. The Inquiry Committee were of opinion that Dr. A. B. had "persistently and without any justification" neglected to furnish information properly required by R.M.O.

---

[1] This is the form which a doctor is required to complete when the Approved Society of one of his insurance patients to whom he has issued a certificate of incapacity asks for a special examination of the patient by a medical officer of the Ministry of Health.

(*b*) On March 4th, 1921, R.M.O. visited Dr. A. B. and found that the medical record cards were being "extremely badly" kept. On Feb. 20th, 1922, R.M.O. again visited the doctor and found the cards "much better kept," 50 per cent. showing medical entries. On April 24th, 1924, R.M.O. visited Dr. A. B. a third time and found that out of 100 cards picked at random only 18 contained any medical entries for the year 1923. The Inquiry Committee were satisfied that if the cards had been properly kept at least three times as many should have contained entries. Out of 389 record cards produced at the hearing, 234, or 60 per cent., showed no entries and only 49 contained medical entries for the period April, 1923, to September, 1924. The Inquiry Committee were of opinion that the figures should have been 90 per cent. and about 196 respectively. Further, no clinical notes whatever had been made on the record cards, even in cases where such notes were obviously desirable. The Inquiry Committee were of opinion that Dr. A. B. had "persistently neglected to make any entries even of his diagnosis in a large proportion of his cases of insured persons."

(*c*) In 46 cases application had been made to Dr. A. B. by the Insurance Committee for the return of medical cards; in 38 of these cases a second application had been made and in 16 a third application. None had been returned. The Inquiry Committee were of opinion that there was no reasonable excuse for this neglect.

(*d*) The following deductions had, prior to the date of the inquiry, been made from Dr. A. B.'s remuneration in respect of his failure to render forms R.M. 2 and to return record cards to the Insurance Committee: May 16th, 1922, £3; Nov. 7th, 1922, £10; April 23rd, 1923, £20; Oct. 8th, 1923, £20. In communicating the three later decisions to Dr. A. B. the Minister had warned the doctor that a continued persistent failure to comply with the terms of service would oblige the Minister to take a serious view of the matter and to consider whether steps should not be taken with a view to the removal of his name from the Medical List.

The Inquiry Committee, while not satisfied that any real animadversion on the manner in which Dr. A. B. had been keeping his medical records had been made by an officer of the Ministry since R.M.O.'s visit of March 4th, 1921, were of opinion that the previous history of the case displayed "a persistent disregard" of the obligations accepted by the doctor and that this was due to "gross negligence and slackness" on the doctor's part. The report concludes thus: "The Committee are regretfully of opinion that in view of Dr. A. B.'s past behaviour, it would appear hopeless to expect him to perform properly in the future the duties imposed on him by his terms of service of keeping and sending in medical record cards and supplying the Regional Medical Officer with information."

Decision of the Minister.

The Minister decided that Dr. A. B.'s name should be removed from the Medical List.

(2) *Failure to Visit; Absence from Surgery.*

Dr. C. D. had 700 insured persons on his list; his surgery hours, as notified to the Insurance Committee, were 9–11 A.M. and 6–8.30 P.M. on week-days except Fridays, and 9.30–10 A.M. on Sundays and public holidays.

(*a*) E. F., a married woman on Dr. C. D.'s list of insured persons, was taken ill, inter alia with spitting of blood, in the early morning of March 11th, 1924. Although messages were left at the doctor's surgery at 9 A.M., midday, and 6.30 P.M. by E. F.'s mother and husband, the respondent did not call. On the following morning the patient's mother again called at the surgery, but the doctor did not visit and the mother thereupon called in another doctor who found E. F. to be suffering from broncho-pneumonia. The Inquiry Committee were satisfied that some if not all of the messages were brought to Dr. C. D.'s notice.

(*b*) G. H., an insured person on Dr. C. D.'s list, had been treated by the doctor during Easter, 1924, for appendicitis. On the morning of June 16th, 1924, G. H. was taken ill with severe pains and, returning from work, called at the doctor's surgery at 10 A.M. The doctor was not at the surgery, and G. H. left a message with the maid and returned home. As the doctor did not call, the insured person's father left a further message at 6 P.M. Dr. C. D. called at 7 P.M., diagnosed and certified appendicitis, and promised to call on the 18th. On the 17th, as G. H. was considerably worse, his father called at the surgery and, having ascertained that the doctor was away until the next day, he left an urgent request for an early visit. By the 20th the doctor had not called, although a letter requesting him to do so had been delivered at the surgery on the 18th. On the 20th another doctor was called in and recommended an operation, which was performed in hospital on July 14th.

(*c*) On July 5th, 1924, the clerk to the Insurance Committee called at the surgery at about 10 A.M.; neither Dr. C. D. nor any other doctor was in attendance and no notice was exhibited to explain his absence. The clerk called again at about 6.30 P.M. and found 24 patients waiting; the doctor did not arrive until 6.30, when he went out to an urgent case and returned in about a quarter of an hour; he then dismissed all but the urgent cases. On July 8th, the clerk called at the surgery at 11 A.M. and at 11.45 A.M., and on the 30th at 10.45 A.M.; Dr. C. D. was not in attendance on any of these occasions and no deputy had been appointed.

(*d*) Prior to the date of the inquiry the Insurance Committee had made complaints against Dr. C. D. with regard to certain irregularities connected with records and prescriptions. The Inquiry Committee, however, rejected evidence of these complaints "subject to the fact that all these matters will be brought to the notice of the Minister."

The Inquiry Committee were of opinion that the Insurance Committee were justified in making their representation, and they recommended that Dr. C. D. be ordered to pay the costs of the inquiry with the exception of the cost incurred by the Insurance Committee adducing evidence under (*d*) above.

Minister's Decision.

The Minister decided that Dr. C. D.'s name should be removed from the Medical List, and an order as to costs was made in accordance with the Inquiry Committee's recommendation.

Note.—In this case the doctor did not attend and was not represented at the hearing, neither did he submit a formal answer to the Insurance Committee's representation.

(3) *Fraudulent Entries in Day-Book under Attendance System of Payment.*

The representation in this case was made by the Local Medical and Panel Committee in an area which had adopted the attendance system for the payment of insurance practitioners. Under this system the remuneration paid to the doctor is calculated on the services actually rendered to insurance patients, as evidenced by entries in the doctors' day-books.

(*a*) Dr. I. J.'s day-book for the quarter ended March 31st, 1924, showed an entry of attendance on March 6th against the name of K. L., a male insured person, with a diagnosis of bronchial catarrh. On March 6th, at the request of the wife of K. L., Dr. I. J. had called to see her young son, at a time when K. L. was not at home. Upon being offered a fee by the wife, Dr. I. J. refused to accept it but asked the wife to call at his surgery with her husband's medical card; when she did so the doctor's assistant, who was present in the surgery with Dr. I. J. and was apparently acting under his principal's instructions, entered Dr. I. J.'s name on the medical card and entered K. L.'s name and address in the day-book. Dr. I. J. then prepared and signed himself a prescription for cod-liver oil and malt on the official form in the husband's name. The doctor again visited the boy on March 9th, but made no entry in the day-book. On March 10th and March 19th Dr. I. J.'s assistant gave the wife a prescription on the official form in her husband's name, but the Inquiry Committee were not satisfied that this was done on the instructions of Dr. I. J. The Inquiry Committee were satisfied that Dr. I. J. had at no time attended K. L., neither had K. L. applied to him for treatment, nor taken any medicine prescribed by him.

(*b*) For the same quarter Dr. I. J.'s day-book contained entries for an attendance and visit to M. N. on Jan. 7th, and for visits on Jan. 14th, 15th, and 21st with a diagnosis of dyspepsia; entries for visits to M. N.'s wife, also an insured person, appeared in the day-book for Jan. 7th, 8th, 12th, and 15th, and for three visits in March. The facts proved before the Inquiry Committee showed that on March 7th, in response to a request from M. N., Dr. I. J. called and examined M. N.'s wife; he did not, however, examine M. N. (who was not at the time suffering from any complaint), and M. N. had neither consulted the doctor nor received a visit from him nor attended at his surgery.

The Inquiry Committee found that as regards both cases Dr. I. J. had "deliberately and fraudulently caused false entries to be made on the day-book sheet." As regards Case (*a*) the Committee stated that apparently the doctor's object was to save the insured person's pocket at the expense of the Insurance Committee, but that they did not regard this as being any justification whatever for the doctor's conduct.

The Insurance Committee found that two further charges were not proved except as to the issue of one prescription without an examination of the patient. They recommended that Dr. I. J. be ordered to pay the costs of the Local Medical and Panel Committee.

Minister's Decision.

The Minister decided that Dr. I. J.'s name should be removed from the Medical List, and that the costs of the Local Medical and Panel Committee, taxed as between party and party, should be paid by Dr. I. J.

Note.—In this case the doctor had sought to retire from the panel on the day preceding the inquiry, and had sold his practice.

(4) *Alleged Negligence in Diagnosis.*

On the evening of June 28th, 1924, O. P., an insured person on the list of Dr. Q. R., called at the doctor's surgery and complained of abdominal pain of some 24 hours' duration and of having twice vomited in the morning of that day. His temperature was 98·6° and his pulse 84. Dr. Q. R. made "a most careful and complete examination" in view of the possibility of appendicitis, and in the absence of tenderness or rigidity came to the conclusion that the patient was suffering from intestinal colic. He prescribed castor oil and a rhubarb and chloroform mixture, ordered the patient to bed, and gave a first certificate of incapacity in accordance with his diagnosis. He made a full note of his observations on the patient's record card. The doctor did not call to see the patient on the 29th. On the 30th, as the pain continued and the patient again vomited, his wife called at the surgery in the evening, when the respondent was not there. She called again later. There was considerable conflict of evidence at the inquiry as regards what took place at this interview between the patient's wife and the doctor. The Inquiry Committee thus summarised their impression of what had occurred: The patient's wife "made known to the respondent that the deceased was still in pain and not better; she made inquiries as to diet and requested the respondent to call and see her husband. The respondent did not offer to call and did not, in fact, call on that evening, but recommended the external application of hot flannel and turpentine." On July 1st the patient's wife left a message at the surgery asking the doctor to call because her husband was worse; the doctor called at about 12.30 P.M. (the second call on his round), and upon examination came to the definite conclusion that the patient was suffering from appendicitis and so certified him. The patient was removed to the infirmary at 2.45 P.M. Some six hours afterwards an operation was performed and the patient died on July 4th from peritonitis and toxæmia. The operation disclosed a swollen and œdematous cæcum, the appendix, which was gangrenous and perforated, lying in a retrocæcal position and tightly bound down.

The Inquiry Committee expressed the opinion that (*a*) in view of the condition disclosed at the operation an early diagnosis would have been difficult and that the risk involved in an operation on such an appendix is greater than in a normal case; (*b*) that there could be no suggestion of negligence or want of care in relation to what happened on June 28th and 29th; (*c*) that as regards June 30th, having knowledge that a person suffering from intestinal colic had not recovered in 48 hours and was still suffering pain, it was the doctor's duty from a professional point of view to take control of the situation and to insist on paying a visit on the evening of that day. On this point the Inquiry Committee were not satisfied that Dr. Q. R. was justified in relying on his own impression of the information furnished by the deceased's wife without assuring himself whether or not some other cause had supervened to explain the continuance of the illness. The report adds: "At the same time we doubt whether the word negligence is apt as a description of the criticism set out in the preceding sub-paragraph. Certainly gross negligence as alleged in the representation cannot be imputed to the respondent. We would rather describe our criticism as connecting an error of judgment as to the urgency of the case having regard to the information possessed by the respondent on the evening of June 30th and the morning of July 1st."

The Inquiry Committee considered that it was quite impossible to attribute the death of the deceased to anything done or left undone by the doctor. While feeling obliged to reject evidence as to the doctor's care and skill in his insurance practice, the Committee "hardly doubt that the Minister would always be ready to receive reports of such good conduct although not based upon sworn evidence." The Committee finally expressed the opinion that the charge of gross negligence put forward in the representation had failed; they added: "We cannot, however, hold that the complainants were not justified in all the circumstances in presenting their representations, and we think that the justice of the case will be met by our recommending that each party should bear their own costs of the inquiry."

Minister's Decision.

The Minister decided that Dr. Q. R.'s name should not be removed from the Medical List and that no order should be made as to costs. In the covering letter communicating this decision the Minister stated that the inferences of fact referred to in (*c*) above indicated "a failure to provide a proper standard of medical treatment" and he accordingly decided to withhold £10 from the doctor's remuneration.

(5) *Alleged Negligence in Diagnosis and Treatment.*

S. T., aged 18, a male insured person on the list of Dr. U. V., had on more than one occasion previously been treated by this doctor for septic sore-throat. On the evening of April 5th, 1924, the patient attended at the doctor's surgery for treatment of a sore-throat. The patient was then suffering from acute follicular tonsillitis but without any marked fever, and the doctor prescribed suitable medicine and treatment, and issued certificates on April 5th, 12th, 19th, and 26th. The doctor visited the patient at his home on April 6th, 7th, 9th, 11th, 13th, 15th, 16th, 17th, 19th, 20th, and 22nd, and during this period continued to treat the patient for tonsillitis. On April 9th the patient showed signs of a broken quinsy. On April 14th he had one single attack of nasal hæmorrhage, and on the night of that day and on two subsequent days suffered from regurgitation in an attempt to take liquid food; the doctor was informed of these symptoms. From about April 15th the patient's speech was affected and on or about April 21st the patient suffered from pains in his chest. On April 26th—the patient then having no temperature—the doctor recommended a change of air, and permitted the patient to be out of bed on the three succeeding days. The patient was worse during the days April 26th to 29th, and was seriously ill when he visited the respondent in the surgery on April 30th. On that day the doctor diagnosed the case as being probably one of diphtheria, mainly owing to a test of the soft palate which showed signs of paralysis. In the opinion of the Inquiry Committee the patient was, in fact, attacked by diphtheria on April 12th or a few days thereafter. Following upon his diagnosis of diphtheria the doctor gave the necessary certificate enabling the patient to be removed to hospital. The patient died from the effects of diphtheria and Vincent's angina. The doctor did not throughout the period of treatment take a swab of the throat.

The Inquiry Committee formed the opinion that the doctor did not suspect diphtheria until April 30th. They considered it impossible to state with certainty that a swab taken at the appropriate time would have given a sure indication of the presence of the disease, but they regarded as unfortunate the fact that the doctor, in his persistent diagnosis of tonsillitis, did not adopt this further test for the purpose of checking his opinion. Apart from any question as to the degree of skill possessed by the doctor, the Inquiry Committee were of opinion that no possible suggestion could be made against him of any neglect in treatment. They thus expressed themselves: "When a charge of gross negligence is made against a doctor it seems just to avoid an attitude of mind which—to use a colloquial phrase—savours of being wise after the event and not to attach undue weight to the death of the patient with the obvious exception of cases in which the death can be proved to be attributable to such negligence. . . . In our opinion the charge of gross negligence wholly fails; we think that the complainants were not justified in making their representation and thus putting in motion the machinery which involved the inquiry heard by us. In pursuance of this view we recommend that the complainants be ordered to pay to Dr. U. V. his taxed costs of the inquiry." The Inquiry Committee drew attention to the marked fairness and impartiality displayed by the Insurance Committee's representative in conducting the case.

Minister's Decision.

The Minister decided that Dr. U. V.'s name should not be removed from the Medical List and that the costs, taxed as between party and party, should be paid by the Insurance Committee. In the letter communicating this decision the Minister stated that he was advised "that some of the symptoms from which, according to the report of the Inquiry Committee, this patient suffered were such as should have suggested the presence of diphtheria to any practitioner exercising a reasonable degree of care and skill in his attendance on the patient with sufficient force to make it incumbent upon him to take such steps as were reasonably open to him to ascertain whether he was justified in his view that the case was not one of diphtheria. The Minister is therefore of the opinion that Dr. U. V., in omitting to take such steps, failed to take precautions which any reasonably prudent medical practitioner would have taken. The Minister is therefore in agreement with the original recommendation of the Medical Service Subcommittee that a substantial deduction should be made from the practitioner's remuneration." A sum of £20 was accordingly ordered to be deducted.

(6) *Miscellaneous Failures to Comply with Terms of Service.*

Dr. W. X. had 2000 insured persons on his list. His surgery was from half to three-quarters of a mile from his house; his surgery hours as notified to the Insurance Committee were: 9 to 10 A.M. on each week-day except Thursday, at his surgery; 4.30 to 5 P.M. at his residence, and 5 to 6 P.M. at the surgery. The doctor had suffered for some years from a dilated heart and angina pectoris; in March, 1924, his condition became worse and he was unable to carry on his professional work for three months.

Various charges were made against the doctor of absence during the prescribed surgery hours on dates in December, 1923, and February, 1924. Several cases were proved where patients had waited at the surgery from 9 A.M. until 10 and 10.30 A.M. before the doctor's chauffeur came to inform them that the doctor would not attend at the surgery on that morning. On one occasion when the doctor failed to attend between 15 and 20 persons waited at the surgery to see the doctor and were not invited to go to the doctor's house. While the Inquiry Committee accepted the doctor's evidence that he was not in a fit condition to take the morning surgery on some of the material dates, they were satisfied that on three dates no message notifying the doctor's inability to attend was sent to the surgery until 10 o'clock or after and that none of the patients was invited to go to his house. They considered that a message should have been sent to the surgery much more promptly, and that, having regard to his condition, the doctor should have made advance arrangements to ensure that his patients were properly attended if he were prevented by sudden ill-health from taking his morning surgery.

On a further charge the Inquiry Committee found that on one occasion when the doctor was unwell he was informed of a patient's illness and was requested to call; he failed to call or to send any other doctor in his place. The Inquiry Committee attributed this neglect to forgetfulness due to ill-health rather than to wilfulness. The Inquiry Committee also found as proved two cases of ante-dating of certificates, six cases where the doctor had failed to supply the Insurance Committee with any record of the treatment of temporary residents, and three instances in which the doctor, without any valid excuse, neglected to furnish the prescribed reports to the tuberculosis officer and R.M.O. The Inquiry Committee were also satisfied that the doctor had neglected to return to the Insurance Committee medical records within a reasonable time after being requested to do so, but they were of opinion that there had been a distinct improvement in this respect since June, 1924. Finally the Committee endorsed a charge that since July 1st, 1924, the doctor had sent to the Insurance Committee 70 medical cards (acceptances) on which the doctor's name had been signed by a lay secretarial assistant.

The Inquiry Committee, in summarising the case, stated: "There is no doubt that Dr. W. X. has been persistently and seriously slack in the observance of the obligations imposed on him by his terms of service and has made a practice of disregarding official communications addressed to him in connexion with his duties. In the view of the Inquiry Committee, the plea of ill-health can only be accepted as a palliation of the doctor's defaults to a very small extent, and the root of the trouble is an ingrained habit of slackness and procrastination."

Minister's Decision.

The Minister decided that the doctor's name should not be removed from the Medical List, but that he should pay the costs of the inquiry and that, having regard to the findings of the Inquiry Committee as to the irregular attendances at the surgery and his other failures to comply with the terms of service, £100 should be deducted from his remuneration. The Minister added that if any further representations were made and established as to the doctor's failure to comply with his obligations as an insurance practitioner, the Minister would have no option but to remove his name from the Medical List.

Reports and Analytical Records.

DE-NICOTINISED TOBACCOS.

(CESTRADA CIGAR AND CIGARETTE CO., 23, PALL MALL, S.W. 1.)

To many smokers, more particularly those who unfortunately suffer from cardiac affections and throat irritation, the suggestion of being able to obtain tobacco from which a portion of the nicotine has been removed is attractive. The Cestrada Company supply such tobacco, and the following are the results of our examination of some of the products sold by that firm:—

Tobacco.	Nicotine, per cent.		Moisture, per cent.	Mineral matter, per cent.	Reduction of nicotine, per cent.	
	On sample.	In moisture-free tobacco.			On sample.	In moisture-free tobacco.
Turkish	1·35	1·57	14·1	17·4	—	—
Ditto, partially de-nicotinised	1·24	1·45	14·7	16·6	8·1	7·7
Virginian..	2·41	2·77	12·7	10·3	—	—
Ditto, partially de-nicotinised	2·02	2·39	15·6	9·2	16·0	13·7
Blended "Dormy" mixture	1·86	2·20	15·4	14·2	—	—
Ditto, partially de-nicotinised	1·48	1·74	14·7	13·9	20·4	21·0

These results show an appreciable reduction in the nicotine content of the tobaccos which have been subjected to treatment. We have submitted the samples to smoking trials and fail to detect any appreciable difference in flavour and smoking qualities between the treated and untreated tobaccos. It is possible that an even greater reduction in the nicotine content could be effected without impairing the quality, and many smokers may find with the use of these tobaccos that they have been undergoing an unnecessary amount of deprivation.

SALODINE.

(THE SALT UNION, LIMITED, COLONIAL HOUSE, LIVERPOOL.)

This is a prepared table-salt over the manufacture of which unusual pains appear to have been exercised. The salt is sold to the public at the same price as ordinary table-salt, and owing to its iodine content is recommended to medical men as specially suitable for goitrous subjects.

ROEBARYT.

(SACCHARIN-FABRIK, RONSHEIM AND MOORE, 11A, WORMWOOD-STREET, E.C. 2.)

This is a new preparation to be used as a meal in X ray diagnosis of the alimentary tract, stomach, and bowel. The difficulties sometimes attended with the use of barium sulphate are well known, and various attempts have been made to overcome them, which have not always proved satisfactory. The production of Roebaryt is a design to manufacture a preparation of barium sulphate which, by mixing with water, will form a stable suspension. A vegetable mucoid material is employed which has the property of producing a viscous mixture which resists breaking up for a prolonged time, thus avoiding the necessity of taking X ray photographs during the actual consumption of the meal. According to the directions, Roebaryt is easily prepared, 150 g. being stirred with about 100 c.cm. of water at any desired temperature, more water being added until the mixture attains the required consistency. The preparation is supplied in cartons for both oral and rectal employment.

THE LANCET.

LONDON: SATURDAY, JUNE 20, 1925.

CHANGING TYPES OF DISEASE.

In their recent addresses to the members of the Inter-State Post-Graduate Assembly of America, both Lord Dawson and Sir Thomas Horder laid special stress upon the opinion, which has been slowly growing up in the many branches of the profession, that a large proportion of our present-day maladies are the product of the rush and jostle of modern life. This conception Sir Thomas Horder closely allies to a further one, and makes some suggestions as to their interdependence. He believes that at the present day we are beset to an increasing extent by infections for which the less pathogenic types of micro-organisms are responsible, and, in fact, that we are becoming "more and more the prey to our saprophytes." This, he further suggests, is a direct outcome of nervous strain. The thesis is an unattractive if stimulating one, but one which, for these very reasons, demands the most careful and staid examination before it can be accepted. That there is an ebb and flow in the severity of certain diseases there is no room for doubting, as a comparison of scarlatina in the time of Sydenham, in the eighteenth century, and at the present day will amply show. What determines these fluctuations we do not know, and a question as to the reason for the decline in incidence of other infections does not find us much better enlightened. Whilst a fuller knowledge of the causation and pathogenesis of typhoid, tuberculosis, and typhus, to name only three of the acute infections, might be expected to contribute mainly to their gradually diminishing incidence, it seems undoubtedly the case that in many such conditions this decrease cannot be truly claimed as a triumph for bacteriology, but that "common-sense" and the ordinary hygienic measures indispensable to the comfort of crowded modern life have initiated this decline, which, in the case of any communicable disease, will tend to go on simply from a reduction of the number of carriers in existence. In such cases knowledge has often advanced *pari passu* with the decline of the disease and has not been, strictly speaking, responsible for it, although no doubt contributing. There is a possibility that in accepting and congratulating ourselves upon the reduction in incidence of such diseases we may tacitly assume a reduction in their severity, simply from the knowledge of a reduced total mortality. In many cases this is definitely not so, and there is no reason to believe that either tubercle or typhoid are any less virulent now than at any time in the period with which we are especially concerned. Granted, then, that certain diseases are declining in incidence, if not in virulence, this is to some extent offset by an increase in other directions. There are, on the one hand, the epidemic maladies, such as influenza, which in recent years has been so severe a scourge, and the less well understood condition of encephalitis whose pathogenesis and transmission are yet unknown; whilst of the more chronic conditions arterial disease and cardiovascular degeneration would appear to be increasingly prevalent.

If we accept, as we are bound to do, the decline of many of the infections and make due allowance for the improved hygiene and régime of modern life—which must be held of paramount importance in this direction—we have yet to ask if this satisfactory state of affairs can be entirely explained on such lines, or does bacteriology offer any further explanation? The ability to answer the question exactly involves a knowledge of one of the most obscure fields in this branch of medicine, and at the present no complete answer can be given. It is possible that in the passage of time bacteria may slowly change their mode of life and tend to move from a position of pure parasitism towards one of symbiosis and ultimately of saprophytism. It has been pointed out repeatedly that the state of ultra-parasitism is not a desirable one from the point of view of the organism's survival, since death of the host will bring in its train death of the parasite and ultimately the extinction of the latter. Thus the hypothesis that certain bacteria may, in the course of their evolution, become modified in virulence, so as better to accommodate themselves to a long life in the tissues of the invaded person, is a not unreasonable one and would connote a change in type and a lessened severity in the disease which such an organism caused. On the other hand, it appears certain that the pathogenic organisms have been originally derived from saprophytes of the same type and that, for example, the typhoid bacillus is a member of the large group of intestinal coliform organisms which has specially developed the parasitic habits and with this its distinctive characters; and, in like manner, the spirochæte of syphilis is probably derived from the saprophytic spirochætes common upon the genital organs. In such ways alterations in the severity of a recognised disease may be correlated with slow changes in the degree of parasitism possessed by its causal organism. Sir Thomas Horder has singled out the condition of ulcerative endocarditis. No doubt the impression gained by clinical and post-mortem experience over a number of years is that the more acute, "malignant," types of the disease are becoming fewer and that the more chronic, or subacute, type, with less clamant symptoms and the occurrence of large non-suppurating infarcts, is on the increase. Although conclusions based upon impressions are notoriously uncertain, in the absence of any available statistical information upon the subject we may, for the moment, accept this. The condition is most commonly a streptococcal infection, and it is significant that of all the organisms studied by medical bacteriologists, the streptococcus group seems the least well defined, the most ubiquitous, and the most mutable. F. W. Andrewes long ago suggested that this group was in an actively evolving condition and pointed to the main types which, according to his classification, seemed to be emerging. Further knowledge supports this view, and because of the uncrystallised condition of the whole group it remains the despair of the systematist. The present period of medicine may well be the period of streptococcal infections, and from erysipelas, puerperal fever, broncho-pneumonia, and scarlatina (for the last of which the evidence in favour of a streptococcal causation is weighty), through such more chronic conditions as endocarditis, and possibly, rheumatism, to the minor infections of teeth and tonsils, we are constantly meeting with the streptococcus in its different grades of activity. The factors controlling its varied degrees of virulence are not understood. Virulence, at the best, is a difficult matter to assay, and the search has been directed more towards the finding of other characters which would indicate this than towards its exact estimation. By various tests the organisms in this great heterogeneous group are being split up into divisions, often ill-defined and with uncertain boundaries, but though progress may be slow a better comprehension of the types of streptococci and their association with types of disease is being steadily worked out.

The further question upon which Lord Dawson and Sir Thomas Horder laid stress is the influence of modern life upon the incidence of the more chronic infections. Here we are upon even less certain ground. All that can be truly said is that there is an association, evident to every mind, between the two, but whether this is a chance association or whether it is a causal one has yet to be definitely discovered. It must also be borne in mind that in connexion with any increase in endocarditis in the war and immediately post-war periods, this upheaval imposed an immense physical, as well as a nervous, strain upon a populace a considerable proportion of which normally followed purely sedentary occupations. The sharp check in the slowly declining death-rate from pulmonary phthisis, which occurred during the war period, may be most reasonably attributed to this physical strain lighting up dormant lesions and accelerating the course of slowly progressive ones. Knowledge of the influence of the nervous system, and in particular of its higher parts, upon bodily resistance and immunity to infections is scanty, and the field for inquiry very large. The way has been pointed and the future will supply the answer to many questions which at present are open.

◆

A NEW ZEALAND EUGENIC INQUIRY.

The New Zealand Ministry of Health has just published the report of a Committee of Inquiry appointed to examine the question of the treatment of mental defectives and sexual offenders in the Dominion. There evidently exists in that country, so justly proud of the virility of its people, a keen consciousness of the number of its mental defectives, their expense to the State, and their prospective increase through uncontrolled fecundity. Latterly, we understand, the accident of a series of sexual crimes of a revolting character has attracted popular attention to the possible connexion between sexual offences and the treatment of mental deficiency. As the Committee's report recognises, these two matters are separate. Some mental defectives show lack of control in sex instincts and functions as in other respects, but not all feeble-minded persons are sexual offenders, nor are all sexual offenders mentally deficient; on the contrary, it is notorious that some offenders of the worst type are often found to be intellectually above the average. The two questions being distinct, the recommendations made by the Committee in respect of each can be summarised separately. Briefly, it is proposed that the criminal law be altered to permit the passing of an indeterminate sentence upon the sexual offender. The court should have full discretion to say whether sentences should be definite or indeterminate; the Prisons Board would have power to recommend release on probation or final discharge in the case of prisoners undergoing an indeterminate sentence. A psychiatrist should be appointed to advise the Prisons Department (and possibly the courts) on the classification and treatment of sexual offenders. The Prisons Board should also be advised in these matters by a new Eugenic Board, which should include a skilled psychiatrist and a member of the medical profession, and be presided over by a magistrate as chairman. Such are the recommendations in respect of sexual offenders.

On the other question—the treatment of mental defectives—the findings and recommendations are more elaborate. The Committee expresses the general view that the unchecked multiplication of the feeble-minded and epileptic continually swells the sum of human misery and the financial burdens of the State, and leads to the serious deterioration of the race. They recommend adding to the New Zealand Mental Defectives Act the definition of "moral imbeciles" contained in the English Act of 1913. Here we hope it will be borne in mind that the medical officers of English prisons find that definition unsatisfactory, since the words "from an early age" involve difficulties of proving the patient's early history, which often result in excluding the application of the definition from cases to which it should apply. The Committee advises the creation of a special branch of the Mental Hospitals Department to deal with all classes of mental defectives who are not inmates of mental hospitals, to develop after-care work, and to keep a complete register of mental defectives, epileptics with dangerous, immoral, or other anti-social tendencies, moral imbeciles, and persons discharged from mental hospitals. The plan of this register—which owes much, we believe, to the suggestions of Dr. Theodore Grant Gray, the medical superintendent of the Nelson Medical Hospital—is that all school medical officers should have a statutory duty to report the names of feeble-minded or epileptic children in their districts; local education authorities would report the names of all children not attending school on account of these defects; hospitals, mental institutions, industrial schools, and reformatories would make similar reports; and finally, every judge or magistrate on convicting persons tainted with mental deficiency or epilepsy would be empowered, subject to confirmation by an alienist, to order the name of the accused to the placed upon the register. The placing of a person's name upon the register would be safeguarded by a right of appeal to the High Court on the part of the person concerned or his or her parents or guardians. Marriage with a registered person should be made illegal, and carnal knowledge of such a person should be an indictable offence. Other recommendations advocate the better use of special classes in schools, residential special schools for children who may benefit by manual training, the registration of inmates of special schools who are found incapable of benefit from further residence therein, and a power for the Eugenic Board to order the removal of feeble-minded persons or epileptics to special farm or industrial colonies. Not the least important recommendation is a more stringent system of investigating the family history of assisted immigrants and a closer supervision of those who enter the Dominion as ordinary passengers. New Zealand does not forget that part of her trouble is due to the careless admission of a low type of immigrant under the expansive arrangements of 50 years ago.

The Committee has a good deal to say on the much debated topic of sterilisation of the criminal and feeble-minded. They quote the cautious views of the Central Association for Mental Welfare of Great Britain that procreation by defectives is by no means the only menace attaching to their presence in the community, that, inasmuch as a sterilised female defective by a life of promiscuity or prostitution may become a virulent source of venereal infection, sterilisation is dangerous without segregation, a dubious advantage if it encourages non-segregation, and unnecessary if segregation is imposed. But the New Zealand Committee does not agree that sterilisation is as yet impracticable. Though in relation to sexual offenders the report confesses that the available information is inadequate for final judgment, in relation to mental defectives it definitely advocates that the Eugenic Board be given power in suitable cases to make sterilisation a condition of release from mental institutions or of removal of name from the register. Persons thus operated upon and liberated should be released on probation with power to reincarcerate them in institutions if they are found to be leading an immoral life or for other sufficient reason. If the Dominion embarks upon this experiment, we shall watch its progress with interest. Our present information, derived from some of the United States of America, is uncertain and incomplete. Some of the States—Indiana for example—passed sterilisation statutes as long ago as 1907. But under the workings of the American constitution (which are hard of comprehension by outsiders) some of these statutes have been declared void, whether as contravening articles of the State's constitution which guarantee to the people "life, liberty, and the pursuit of happiness," or as infringing the constitutional objection to "unreasonable classification," since persons confined in State institutions are less apt to have children than the greater number of persons no more fit who, because of the prosperity of their parents, can be at liberty. In many case the statutes have remained a dead letter. Recent statistics are not available, but it is stated that four years ago there were 120 State institutions legally authorised to perform the operation of sterilisation, and that only 31 of these had made use of that authority. In the absence of definite experience New Zealand does well to move without precipitancy. We note that the Committee proposes no such operation be performed without the consent of the parents or guardians of the patient. The proposals will, of course, require an Act of Parliament, and the main difficulty of administering the Act will be the fixing of an exact standard of mental deficiency.

A MEDICO-LEGAL INSTITUTE.

THE annual general meeting of the Medico-Legal Society will be held on Tuesday, June 23rd, at 8.30 P.M., at the Royal Society of Medicine, 1, Wimpole-street, W., when advantage will be taken of the occasion to consider the suggestions of a Committee appointed by the Council of the Society upon the foundation of a Medico-Legal Institute in London. A summary of the suggestions of this Committee runs as follows:—

1. That it is desirable to have a Medico-Legal Institute in London for the investigation of medico-legal cases, and for the control of the teaching of Medical Jurisprudence.
2. That such an Institute would be available for the carrying out of medico-legal investigations for the whole of England and Wales if required, until similar institutes were established outside London in University centres in England and Wales.
3. That for the purposes of Medico-Legal investigation and research the Institute should be under the control of the Home Office, and that for the purposes of teaching, the Board of Education, the University of London, and the Royal Colleges of Physicians and Surgeons should exercise control.
4. That a Medico-Legal Museum should be formed in the Institute.
5. That the Medico-Legal Institute should provide facilities for the post-mortem examination of bodies sent to the Institute by coroners (these cases being used for teaching purposes). The Institute should provide specially trained experts from its staff, who, at the request of a coroner, would be available for making post-mortem examinations in any district.
6. That the medical staff of the Institute should be composed of a certain number of full-time experts—e.g., a director of the investigations, the holder of the Chair of Medical Jurisprudence, a toxicologist and a bacteriologist, and of a certain number of part-time experts, preferably those engaged in pathological work.
7. That the association of the Institute with the University of London would afford facilities for consultation with the professors of the different branches of Science and Medicine in the University.
8. That the Institute having a full-time staff, and possessing valuable medico-legal specimens, would afford special facilities for research.
9. That the Institute would be in the best position to provide adequate instruction for medical students in London, and would be a valuable centre for post-graduate teaching and for the training of medical men for posts such as that of police surgeon.

The proposals thus formulated open up for discussion a subject of considerable importance. The cases which in courts of law bring medical practitioners into contact, and sometimes into conflict, with members of the legal profession, are such that in the public interest they should secure full consideration in all their aspects. Those most directly concerned as parties vary from accused persons whose lives are in jeopardy, to others whose interest it is to secure personal damages in respect of physical disability, and the aim sought is ever the same, that justice should be done. It may safely be said that this can only be achieved through medical men, usually present as witnesses, and lawyers engaged as advocates, having the best possible training available for the parts that they have to play and appreciative knowledge of the issues involved. On ordinary occasions it has frequently appeared to us that the medical man has grasped the legal aspects and issues that have to be considered more fully and with a better sense of their import than the barrister or solicitor or possibly the judge, is able to do with regard to the medical points raised. No doubt in this the doctor has the simpler task of the two, and presumably the scheme of the Medico-Legal Society's Committee is prompted by a desire to provide education in medical jurisprudence for the benefit of solicitors and barristers, as well as of doctors. If this is so, the Council of Legal Education might be included among the controlling educational bodies.

In its general aspects the scheme should prove attractive to medical men and students, who will see in it a promise of post-graduate instruction and efficient training and of the provision of scientifically compiled records, illustrated by examples, of phenomena outside their normal experience. The supply of experts authenticated as such by a central body carrying official weight, may be found of considerable value by others, besides coroners, seeking expert advice and assistance. The problem of financing such an Institute has apparently not yet been tackled. This may not prove a serious one, since the public already is interested. The general attention aroused by some recent murder trials, the Harnett case, and the Bateman appeal, has not been evoked only by a morbid desire to be thrilled by details of "human interest." The public has seen that in questions of medical opinion the law and medicine are not always in accord, and their practitioners not always in sympathy. The founding of a Medico-Legal Institute should therefore meet with a substantial measure of general approval, if it is realised that the ultimate object of medical jurisprudence as a study is that justice should be done with the utmost possible certainty and efficiency in the many difficult and doubtful cases in which medical evidence is a determining factor.

Annotations.

"Ne quid nimis."

OUR DEFENCE AGAINST SMALL-POX.

IT seems superfluous to rehearse once again to our readers the arguments in favour of vaccination, when medical men as a body are fully aware of its value and vital importance. The existence of a small number whose conviction is lukewarm may be ascribed very largely to the effects of vaccination itself. So successfully has Jenner's discovery been applied that most of the present generation—doctors and laymen alike—have no conception of the horror of small-pox when it ravages unchecked. Race memory is short, and already the majority of laymen have forgotten why it was that their forefathers, a few generations back, willingly faced the risks of inoculation with the virus in order that they might live the rest of their lives free from the menace of the contagion. It is well to be reminded of these things, as the officials of the Research Defence Society realised when asking Dr. R. A. Lyster, medical officer of health for Hampshire, to speak on this subject at their annual meeting. Dr. Lyster illustrated the high incidence of small-pox by certain local records that have survived from pre-vaccination days. Kilmarnock from 1728 to 1764 had an average population of 4000, and 16 per cent. of all deaths were due to this disease. The mortality was mainly among young children, only three deaths occurring in persons over 20. A census taken at Chester in 1775 showed that only 1060 out of 15,000 persons had escaped small-pox. In Ware, in 1772, 2213 out of 2515 people had had the infection. As everyone who has investigated the subject knows, the statistical evidence in favour of vaccination is overwhelming. Dr. Lyster quoted a number of typical figures, such as those of the recent Toronto epidemic, where 71 per cent. of the unvaccinated victims died, while no person vaccinated within 12 years took the disease at all. Certain antivaccinators have ascribed the decrease in small-pox to the improvements of modern sanitation. Yet the medical officer of health for Gloucester at the time of the 1895 epidemic specifically noted that the area most seriously affected was newly built and but sparsely populated. In Dr. Lyster's opinion, the struggle against disease has been constantly hindered by the acclamation of universal panaceas, sanitation being an instance, but the universal panacea will never be discovered, because each disease has its own particular secret. Science has revealed this secret in certain cases, of which small-pox is one, and there can be no excuse for allowing such diseases to continue in civilised communities. Everyone who has tried to debate the question of vaccination with the antivaccinationist has experienced Dr. Lyster's trouble in finding any scientific basis for their position. Most people will probably agree with him also in crediting them with high ideals and good intentions; the difficulty is to find some common ground for argument. Dr. Lyster concluded his address by throwing out a specific challenge to them to prove their faith. He asked if they would provide 24 volunteers who had not at any time received the protection of vaccination and who would enter into close association with severe cases of small-pox, taking any other prophylactic measures they chose. Any medical school, he was sure, would produce 24 vaccinated volunteers willing to take the same risks. It would be most satisfactory if the two parties could get together over some such definite scientific experiment. The present condition of partial vaccination is, as he pointed out, most expensive for the country; the 1895 Gloucester epidemic alone cost over £150,000 to the public funds. It would be an economy to spend a moderate sum on education of the doubting. One valuable form of education, as Dr. Fraser Harris suggested in moving the vote of thanks, would be to teach the history of scientific discoveries as part of the school curriculum. The education of the adult is being carried out, so far as its very limited funds permit, by the Research Defence Society, which deserves the support of all medical men and needs further donations and new members.

METROPOLITAN HOSPITAL SUNDAY FUND.

HOSPITAL Sunday will be held this year on June 28th, and a 4-page leaflet has been issued by the Metropolitan Hospital Sunday Fund setting out in statistical form a year's work in the hospitals and medical charities of London. This leaflet will serve a useful purpose in bringing prominently before the contributing public the vast amount of work done by our hospitals and their urgent need for financial support. Under the headings of the various districts of London actual figures are given of the number of beds to be occupied, the number of patients treated, and the available income. A short summarised table shows that 179,616 patients were admitted into the voluntary hospitals of London during the year 1924 and that the attendances in the out-patient departments and dispensaries numbered 7,429,183, the total cost being £2,887,778, towards which patients contributed £860,782, and it is interesting to compare this last figure with that for 1913, when it was £105,434. The ordinary income amounted to £2,590,378. The legacies received in 1924 amounted to £484,935. The average number of in-patients daily under treatment was 11,234. The information affords a text for clerical and lay sermons.

HELMINTHIASIS IN THE EGYPTIAN ARMY.

WORM infestation is very prevalent in Egypt. Out of its population of 13 millions 29,000 persons were treated in 1923, voluntarily, in the four anthelmintic annexes of general hospitals managed by the public health department. In the same year 75 per cent. of 1264 recruits for the army, 68 per cent. of 2352 serving soldiers, and 20 per cent. of 150 cadet officers were found to harbour these parasites, chiefly ankylostoma and bilharzia. Great is the consequent loss to the army and the State by sickness and invaliding, wherefore Major B. H. H. Spence, R.A.M.C., serving with the Egyptian Army, and in medical charge of recruiting, decided that it was time to deal with these worm diseases of recruits by mass diagnosis and treatment. He had his difficulties. Some urged treatment should be left till the men complained, some that treatment was unnecessary as a number of men did recover naturally, others that this was not the duty of the army but of the public health department. There was little objection from the army, whose senior officers felt the loss of a few days during treatment was nothing in comparison with the possible benefits. It was proposed to begin with 300 police recruits at Abbassia. The Egyptian commandant objected to experiments being carried out on his men, and only the urgently solicited support of the Ministry of the Interior carried the project through. The fæces and urine of the recruits were examined; those with ankylostoma got, next morning before breakfast, 5 c.cm. of carbon tetrachloride, and two hours later ½ oz. of magnesium sulphate. The after-effects were strikingly mild, far less than with thymol or oil of chenopodium; this treatment is also cheaper. Three months later 75 per cent. of these men remained completely cured. Those who had bilharzia ova in stools or urine got intravenous injections of sodium-antimony-tartrate on alternate days, three times a week for four weeks, 21 gr. in all. Here, again, symptoms were very slight, and 95 per cent. remained well three months later. The cost of treatment was under 1s. a head. The improvement in health of these recruits was so striking that within six weeks the entire permanent staff of the depôt had asked to be examined and treated, and, better still, the commandant, who had at first objected, admitted he had never before seen any batch of recruits remain so fit under training, and benefit so rapidly from it. Indeed, he talked so much and so enthusiastically about it that it was heard of by the King of Egypt, who ordered that his bodyguard should be examined and treated forthwith. In all, treatment was extended to 1214 serving soldiers, while 969 were told off to be treated when the training period was at an end. The reports from regiments were that recruits this year did not faint on parade, nor did they, as formerly, complain of schistosomiasis. This very interesting story is detailed by Major Spence in a thesis for the degree of M.D. Edin., which appears with illustrations in the *Journal of the R.A.M.C.* for May, and is well worth reading, particularly if taken along with his previous paper, on the Wady Halfa Quarantine to protect the Sudan against worm-infected labourers from Egypt, in the same publication for last November.

DUODENAL CATHETERISATION.

THE merit of being the pioneers of this method of investigating the contents of the duodenum belongs, perhaps, to J. C. Hemmeter and Max Einhorn. Various observers have from time to time modified the procedure and the nature of the instruments required, and recently Dr. Alberto Trossarelli has published the results of his work in this respect at the Mauriziano Hospital at Turin.[1] He makes use of a rubber tube of 5 mm. diameter and 1·25 metre long, with a metallic perforated extremity. The tube is filled with an emulsion of barium sulphate which by rendering it opaque facilitates its passage by means of the screen across the stomach and through the pylorus, which is induced to relax by the introduction of sodium bicarbonate according to Jutte's method. The duodenum is reached rapidly, and by means of an ordinary glass syringe the barium emulsion is aspirated first and then the duodenal fluid; the small quantity of the former which remains in the tube in no way interferes with the ultimate investigations. The method is valuable both from a clinical and therapeutic standpoint.

As a rule, the duodenal contents consist of the duodenal juices, bile, and pancreatic juice, but by injecting 25–30 c.cm. of a 25 per cent. solution of magnesium sulphate contraction of the gall-bladder ensues and at the same time relaxation of Oddi's sphincter. Bile thus obtained may be of normal aspect or thick and dark, indicating the presence of cholecystitis, or containing a large quantity of mucous flakes, evidence of catarrhal jaundice. Fine sand points to biliary lithiasis, while a definite amount of blood suggests the presence of a growth either in the duodenum, biliary passages, or pancreas, and especially in the latter organ if the liquid is colourless, and there has been no colic and if pancreatic ferments are absent. Microscopic examination of the extracted fluid sometimes discloses the presence of a large quantity of polynuclear leucocytes with red corpuscles associated with mucus and cellular elements and various micro-organisms; such a condition indicates some inflammatory process, cholecystitis or choledochocystitis either simple or calculous if there are many cholesterin crystals seen. In catarrhal jaundice there may be an enormous quantity of epithelial cells accompanied by polynuclears and cylindrical cells of the biliary ducts. Chemical examination will show that there is complete absence of urobilin in obstructive jaundice, while on the other hand, it is increased in cases of abnormal destruction of red cells such as in hæmolytic jaundice, pernicious anæmia, and malaria. Usually the amount of albumin in the bile varies largely from case to case, and also in individuals who subjectively and clinically may be considered normal, and even varies in the same individual, according as the bile comes from the gall-bladder or biliary passages. Although some observers have claimed that the presence of a definite quantity of albumin is an indication of inflammatory processes of the bile passages, and particularly of catarrhal jaundice, Prof. Trossarelli's researches seem to show that the presence of albumin in the bile is an unsolved problem as an element of diagnosis and cannot be relied on in the absence of other symptoms. In fact, there are individuals who have never suffered from any kind of gastro-intestinal or hepatic disturbance whose bile contains as much albumin as those suffering from jaundice of various kinds. Examination for the presence of pancreatic ferments, diastase, trypsin, and steapsin has failed to afford any definite diagnostic help, partly because the duodenal fluid rapidly loses its fermentative power, whether kept in ice or in a thermostat at 37°C., and partly because the presence of bile largely increases its activity. It is only with the greatest circumspection that it is possible to admit a functional debility of the pancreas in the sense of a diminished excretion of ferments based on a quantitative examination of these substances in the duodenal juice.

Catheterisation is also useful in treatment, since by means of the tube various remedies can be brought into contact with the duodenal mucosa without having to pass through the stomach. One method of treatment which has given good results, particularly in cases of cholecystitis, hepatic calculus, ulcerative colitis, and in some cases of ankylostomiasis, consists in free duodenal lavage with astringents and antiseptics. Among the substances which have been used beneficially may be mentioned argyrol and protargol in 0·75 per cent. to 1·5 per cent., nitrate of silver 1 in 20,000, sulphate of magnesia and Jutte's solution, the latter composed of 0·9 per cent. sodium sulphate and 0·9 per cent. sodium chloride, using 1 to 1½ litres for a lavage. Excellent effects seem to have been obtained by these methods, resulting in the elimination of large quantities of biliary sand and even small calculi with disappearance of symptoms. In other cases, individuals suffering from intermittent fever of obscure origin, where after catheterisation the duodenal fluid was found to contain bacilli belonging to the paratyphoid group, a complete cure was obtained after two or three washings. This method has also been used with solutions of novarsenobenzol in syphilis and emetine in amœbic dysentery. Recently Bottner and Verner practised duodenal lavage with decoction of linseed and 5 per cent. magnesium sulphate in patients affected with pernicious anæmia. Out of six subjects treated they obtained clear improvement in five of them. Prof. Trossarelli's observations and researches demonstrate the great importance that duodenal catheterisation may acquire in the diagnosis and treatment of certain diseases of the liver, bile-ducts, pancreas, and duodenum. When technical difficulties have been overcome it will doubtless obtain its fitting place in practical medicine.

HOSPITAL PROVISION FOR CHRONICS.

NOT long ago Dr. E. P. Boas, medical director of the Montefiore Hospital in New York, brought to the notice of the New York Academy of Medicine the problem of the hospitalisation of the chronic case. There are, it appears, few institutions in New York where adequate care is given to the treatment of chronic disease, and at existing institutions there is little if any differentiation made between cases simply requiring custodial care and those which would respond to specialised medical and surgical treatment. The subject is further dealt with in a report by the Public Health Committee of the Academy which has just reached us. The type of case for which the New York hospitals under present circumstances do not arrange includes the various rheumatic diseases, cardiac and visceral troubles of many kinds and degrees, mucous colitis and other gastro-enteric diseases which do not readily respond to home treatment, disturbances of the neuro-muscular system, renal affections and the large group of orthopædic cases. Shelter is provided for those who have reached the incurable stage, but the need is felt for the care of those who are not yet hopeless. The staff should it is argued, be made up only of physicians who are interested in the study and treatment of chronic disease. In a recent survey,[1] made at the instance of the same public health committee, it is stated that there are only three hospitals in New York with an entirely independent staff of physicians for the out-patients' department, and two of these are now contemplating a reorganisation which will bring about closer coördination between the hospital and the dispensary work. The survey closes with a definite indictment of the lack of "community policy," which, it is stated, has resulted in a heterogeneous accumulation of hospital services more or less suited to the needs of the community, but inelastic in their organisation, not fully adjusted to meet the economic status of the several classes of the population, and for the most part not coördinated with the existing hospital facilities in the city as a whole. This is an indictment which, with necessary amendments, probably applies to most hospital services everywhere, and one of the great works of the not distant future will be the removal of a state of things almost inevitable in the past, but which is now in danger of becoming an avoidable reproach.

UNPLEASANT BOOKS.

THE 135th anniversary dinner of the Royal Literary Fund was held at the Hotel Victoria on June 11th, when the Spanish Ambassador, Don Alfonso Merry del Val, presided and made in idiomatic English an admirable speech on the position of English literature in Spain. He spoke, he insisted, as a diplomatist representing the views of the Spanish sovereign, but the training of the English public school was apparent throughout. To the toast of literature proposed by Sir Robert Kindersley, Major Ian Hay Beith responded in eloquent terms, pleading the cause of all writers great and small and apologising for "a great deal of stuff that is about" by pleading that the unpleasant books for which there is a mania in certain circles represented a passing phase and one at which many people were already bored. Major Beith was as serious as he was funny in his excellent speech, and he put unpleasant books, we think, in their right place as a transient nuisance. Medical men at least must hope so, but this implies that the propaganda of the voluntary custodians of public morality must often advertise what had better have been ignored. The mass of illiterate readers—and the mass will always be illiterate—is only stirred to emotional attention by the primary human needs of birth and death and mating. The writer whose style falls just short of the living touch may gain effect by overstepping ever so little the conventional bounds of plain speaking and by producing the first degree of shock, which may be pleasant. The fact that the second degree brings nausea and satiety should not be forgotten.

THE MATHEMATICS OF INTERNAL RESPIRATION.

ON June 10th Prof. L. J. Henderson, of Harvard, delivered the first of a series of three lectures upon Blood as a Physicochemical System in the Physiological Institute of University College, London, Prof. A. V. Hill being in the chair. The size of his audience may be explained by the memory of a lecture before the Physiological Society in 1920, at which Prof. Henderson introduced his own particular method of attacking the physicochemical properties of the blood. The present series of lectures record progress made during the intervening five years. The lecturer began by summarising the various physicochemical investigations already performed on the blood. He pointed out the great importance of the work of J. Barcroft upon the dissociation curve of oxyhæmoglobin, since it demonstrated that one of the most important respiratory functions of the blood could be reduced to a mathematical problem. The subsequent investigations of A. V. Hill proved that it was possible to express the conditions in the form of a simple and now familiar equation. The next investigations of importance were those of Christiansen, Douglas and Haldane, who made clear the marked difference in the carbon dioxide absorption between oxygenated and reduced blood. Van Slyke, Wu, and F. C. Maclean's investigations of the various alterations in the water content of cells and plasma were also summarised. Prof. Henderson then described his own investigations into the relations between free, total, and fixed CO_2 of the blood, concluding that the following variables constituted the main factors in the physicochemical equilibrium of the blood: free oxygen (O_2), total oxygen (HbO_2), free CO_2 (CO_2), total CO_2($BHCO_3$) hydrogen-ion concentration of serum (H), volume of corpuscles (V), and the ratio of the anions within and without the cells (r)—i.e., Donnan's equilibrium factor. Previous work had suggested that these variables might be grouped in threes, when it would obviously be possible to define the five following equations:—

$$\begin{aligned}
&f_1.\ (H)\ .\ (H_2CO_3)\ .\ (BHCO_3) &= 0.\\
&f_2.\ (O_2)\ .\ (HbO_2)\ (H_2CO_3) &= 0.\\
&f_3.\ (H_2CO_3)\ .\ (BHCO_3)\ .\ (HbO_2) &= 0.\\
&f_4.\ (H)\ .\ (HbO_2)\ .\ (r) &= 0.\\
&f_5.\ (H)\ .\ (HbO_2)\ (V) &= 0.
\end{aligned}$$

The possible permutations of the series evidently preclude any attempt at algebraic solution. Prof. Henderson's thesis might be summarised by stating that he believed that if some solution could be offered to these equations, the conditions of the blood's equilibrium would be defined. There are seven variables, and it ought to be possible, by fixing any two of the seven, to define the other five. In his second lecture Prof. Henderson dealt with a method of solution by means of a graphical representation on the following principle. A series of curves for the five equations can be plotted on the basis of two of the variables being fixed, and by superimposition a comprehensive diagram thus obtained. The result, however, would be a mass of confusion if the ordinary type of graph were constructed. Prof. Henderson has called to his aid the Cartesian nomogram, extensively used in mathematical circles, which has, in his hands, yielded information of the greatest value. To construct a nomogram for the equation $x+y=z$, the ordinate and abscissæ are first graduated in terms of x and y. The numerals on the co-ordinates are joined by means of straight lines with the result that a series of diagonals are produced, joining like values of x and y. These lines are numbered according to the values which they unite. To use the nomogram, perpendiculars are dropped from the particular values selected for x and y on the co-ordinates, and it will be found that the point of intersection will lie on one of the diagonals or contour lines. This will correspond to the value of z. By superimposing a series of contours upon such a Cartesian background it is possible to read off the points of intersection.

THE CONTROL OF THE TSETSE-FLY.

As against the hope expressed at the recent League of Nations Conference on Sleeping Sickness in Africa, that international coördination would do much to further progress in combating this disease, Prof. Warrington Yorke has rather focused attention on our own "kail-yard" in his paper read to the Imperial Entomological Conference on June 15th. In this paper he put forward a case for coördination of effort among our own African colonies in tsetse-fly investigation, principally in the experimental determination of the relationship of game to fly. The problem, he said, was to coördinate the four factors concerned in the disease—namely, (1) the pathogenic virus or trypanosome; (2) the population and the domestic stock; (3) the transmitting agent or tsetse-fly; and

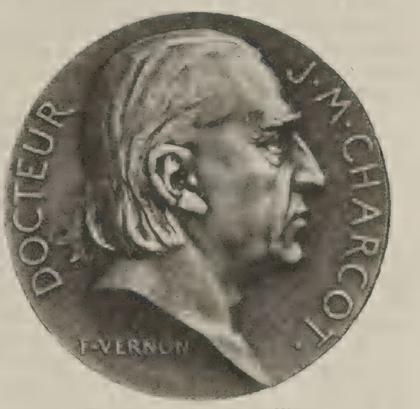
---

[1] The Hospital Situation in Greater New York. G. P. Putnam's Sons. Pp. 356.

(4) the reservoir of the virus, or big game. "I do not hope for much," he said, "from the labour of the International Conference. Such a conference seems to me to be premature. I cannot believe that its efforts are likely to advance knowledge, and we hardly know enough at the present time to formulate regulations governing the international frontiers in tropical Africa. In my judgment much more is to be hoped from an inter-colonial conference and from the coördinated and sustained effort which it would be in the power of such a conference to ensure." The main difficulty, as he pointed out, which at present bars the way of progress in the investigation of the ravages of the tsetse-fly, is that energy is often misdirected; first, in that reports from isolated investigators frequently omit some essential information and thus do not permit of any inferences being drawn; and secondly, in that work, admirably conceived and executed, is often brought to naught by the fact that those who are conducting it go on leave without arrangements being made to carry it on. Further, it is sometimes difficult to realise the natural difficulties in the shape of marauding big game with which lonely investigators, inadequately supported by funds and personnel, have to contend, and Prof. Yorke is emphatic that the only hope of success is by substituting for isolated workers, whether entomologists or pathologists, large and well-equipped commissions having real funds at their command. He again urges, as he did five years ago at the first Entomological Conference, that entomological, medical, and veterinary research into the trypanosomiasis problem should be combined under one central organisation, supported by pooled contributions from all the African colonies interested, with adequate precaution to ensure continuity of work. Only by concentrating energies can experimental work be undertaken on a scale large enough to determine the relationship of fly and trypanosomiasis to game, and to solve the various problems enumerated in the report of the Glossina Sub-committee of the Imperial Bureau of Entomology. Prof. Yorke's stimulating criticism will, no doubt, receive respectful attention.

THE CHARCOT CENTENARY.

A SOCIAL evening of the Royal Society of Medicine was held on June 15th at 1, Wimpole-street, in celebration of the centenary of the birth of Jean Martin Charcot. Sir StClair Thomson, the President, in his prefatory remarks extended an especial welcome to several colonial and foreign guests who were present, and read a letter of appreciation to the Society from the Académie de Médecine of France. Dr. Farquhar Buzzard, President of the Section of Neurology, then gave a paper on the great French neurologist. After briefly indicating the milestones in Charcot's life, Dr. Buzzard said any spectator of the recent centenary celebrations held in Paris could hardly fail to wonder what manner of man this Charcot was, who still held, 32 years after his death, the esteem, the gratitude, and the affection not only of his professional pupils and successors, but of his countrymen at large. At a reception in the amphitheatre of La Sorbonne, at which the President of the French Republic was present, the proceedings were enthusiastically followed by an audience of between two and three thousand people, the majority of whom were not medical. From all corners of the earth pilgrims had come to listen and to add to the eulogy of the great neurologist. It was, he said, perhaps the most wonderful tribute ever paid to any medical man—not as a scientist, not as the author of some epoch-making discovery conferring lasting benefits on humanity, just a physician whose work and personality had made an imperishable impress on the science and art to which he had devoted his talents and his life. And, he added, it would be difficult to visualise our public and our Government joining so whole-heartedly in commemorating the birth of even a Jenner or a Lister; it might be doubted whether any medical man had ever been to any country what Charcot had been—and still was—to France. He continued: "Here was a man who, having been appointed quite early in his career chief physician to a large infirmary, the Salpêtrière, spent his life and energies in the service of the institution with the result that from being a building of merely historic and charitable interest it became the foremost school of neurology in the world. And yet Charcot has no great discovery to his name. The enormous amount of material which lay ready to his hand and which illustrated every form of advanced disease he studied not only in minutest detail, but with the artist's flair for accurate observation, for picking out essentials, and for giving them their due perspective. In an era devoted chiefly to the collection of pathological specimens and clinical observations he was second to none of his contemporaries as a collector, and he excelled all in his marvellous gift for marshalling the results of his labour and for giving them graphic presentation whether by pen or by word of mouth. It is not mere patriotism which makes us hesitate to place him beside Hughlings Jackson as a deductive philosopher, but we can boast of no physician who, in addition to making countless contributions to scientific knowledge, can compare with Charcot in his ability to attract students from all over the world by means of his inspired gift for exposition." To give orientation to Charcot's life and work it must be remembered that he was about 20 years younger than Duchenne, of Boulogne, who might rightly be regarded as the founder of French neurology. Duchenne and Charcot were to French neurology what Laennec and Trousseau were to French medicine as a whole. It might almost be said that Duchenne and Charcot discovered and entered a new field in which a rich harvest lay ready for the gathering. Dr. Buzzard then gave many intimate and vivid glimpses of Charcot at home and in hospital, and showed on the epidiascope several interesting portraits, including the centenary medallion, after the design of Mons. F. Vernon, the author of the Osler plaque. He also showed examples of Charcot's skill as a draughtsman and as a caricaturist.



The Centenary Medallion.
Reverse: Centenaire de la Naissance de J. M. Charcot, 1825–1925.

A vote of thanks to the lecturer was moved by Sir David Ferrier, who had himself been a pupil of Charcot over fifty years ago in the Salpêtrière. He referred to his master as one who had made an old poor-house ward into the most visited and most famous clinic in the world. A feature of the evening was the display, in the library, of books, documents, and drawings relating to Charcot and his work which had been prepared by Mr. Walter G. Spencer, the librarian. To his labours Dr. Buzzard paid a special tribute, and expressed the hope that the valuable collection which had been assembled might reach a wider public in some permanent form.

Sir James Berry was among those admitted to the honorary membership of the Inter-State Post-Graduate Assembly of America on June 4th.

ARRANGEMENTS for the International Congress of Radiology, to be held in London on July 1st to 4th, are now complete. Details of the advance programme will be referred to in our next issue.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXVII.—THE TREATMENT OF HAMMER-TOE.

Part II.—Operative Measures.

One difficulty in these small operations is that of access. The operation must be done delicately, and a dressing applied which maintains complete correction without being cumbersome. To fix the deformed toe, and to hold the toes on either side out of the way, a stout fishing gut suture is passed through the pulpy end of each of the three toes. The ends of each suture are gathered up in three separate artery forceps, and the toes held rigidly and firmly out of the way of each other by the assistant. At the end of the operation, when the dressing has been applied—the toe-tip being left uncovered in order to watch the circulation subsequently—the retention sutures are removed. To assist precision and delicacy a rubber bandage should be used as a tourniquet, applied immediately above the ankle after the foot has been exsanguinated by a similar bandage, and is not removed until the dressing is dry and set. The best dressing is sterile ribbon gauze of the same width as the length of the toe, applied directly to the wound (which is sewn up with two or three fine interrupted fishing-gut sutures), and wound around the toe moderately firmly and closely (but without risk of strangulation), with thick collodion applied as the layers are increased. About a dozen or so layers are requisite, and the retention sutures hold the toes corrected for a few minutes while the collodion dries. The "splint" is rigid, and the circulation is noted to be satisfactory in the uncovered toe-tip before the patient leaves the theatre.

The dressing does not shrink subsequently. It is maintained for two weeks, and then cut off with strong scissors, and the skin sutures removed. A similar dressing is applied, and renewed again in another fortnight, taking six weeks in all. The patient can walk a week or two after the operation in this dressing, which is so rigid and small that the walking is harmless and comfortable. Another advantage of the sealed dressing is the avoidance of the thickening of the joint which is liable to persist for many weeks if an ordinary gauze dressing be used.

Excision of Head of Proximal Phalanx, with Removal of Cartilaginous Base of Middle Phalanx.

Of the several operations that have been advised from time to time for acquired hammer-toe excision of the head of the proximal phalanx, combined with the removal of the cartilaginous base of the middle phalanx, is to be preferred. No flexor tenotomy or division of the flexor capsule is done, and only just as much of the head of the proximal phalanx is removed as will enable the toe to be made *quite* straight on strong passive stretching into extension. There should be no tension tending to reproduce flexion when the operation is finished. An ankylosis (arthrodesis) of the proximal joint is desired. If the base of the middle phalanx is left untouched, fibrous rather than bony ankylosis is likely to result, with some risk of recurrence of the flexion deformity. The dorsal incision is elliptical, of about three-fifths the width of the toe, and the redundant skin with the dorsal corn is removed. There is no need to damage the lateral digital arteries. If the deformity be severe, the dorsal expansion of the extensor tendon should be removed with the elliptical piece of skin; if not, it may be preferable merely to incise the tendon longitudinally, to give access to the head of the bone. But the excision is more difficult to do delicately in this case. The head of the bone is best removed by fine-pointed bone-cutting forceps, and the neck of the bone need not be fragmented. A fine chisel or stout, small knife is used to denude the base of the second phalanx of its cartilage. The skin suturing helps to maintain subsequent correction.

In operating on the congenital type, the proximal or terminal joints are similarly corrected, according to the site of greater flexion. It is never necessary to correct both joints. To correct the adduction and rotation of the terminal (one or two) phalanges, the elliptical excision of the skin will be placed somewhat to the outer side of the joint, at the site of the maximum bend. The dorsal expansion of the tendon is removed. In these tiny toes the joint excision is best done with a small, stout scalpel. The skin wound can be sutured in such a way as to assist in correcting flexion, adduction, and rotation. Two or three toes can be operated upon at the same time.

Alternative Operations.

The alternative operations may be mentioned. Amputation of the whole second toe in the acquired variety is not usually desirable unless its terminal nail portion is grossly deformed, or the toes on either side so rigid in their position that there will be no longer room for the corrected toe in its proper place, or unless, as in neglected cases, lateral corns exist. The objection to total amputation is that the frequently associated hallux valgus is liable to increase subsequently, from pressure of the stocking and want of the preventive effect of the second toe. Amputation of the terminal phalanx alone would in most cases leave an awkwardly dorsiflexed proximal stump. In some cases, however, where the hammer deformity is not giving trouble from pressure on a dorsal corn, but where the nail is thick and distorted, with painful terminal corn, the terminal phalanx can be amputated at the end joint, with removal of the bone and nail bed, by the palmar flap method.

Total removal of the proximal phalanx has been advocated, leaving a short, stumpy toe which would serve to prevent the hallux valgus from increasing, but with no other function. The writer has no experience of this method, nor does it appeal to him. In milder cases of acquired deformity, subcutaneous division of the flexor tendons and capsule may be done, followed by passive correction and splintage as after the open operation, but there is some risk of relapse. Flexor tendons do not unite after tenotomy, and thus the only important function of the toes, flexion, is permanently lost, which is not the case after excision by the dorsal method.

In any operative method extension contracture of the metatarso-phalangeal joint must also be overcome by subcutaneous division of the extensor tendons, otherwise relapse into flexion at the distally corrected joint is fostered. After the tenotomy the toe is forced into flexion at the metatarso-phalangeal joint, and retained thus in the dressing while the joints of the toe are kept fully extended.

Correction of "Clawed" Toes.

In the correction of "clawed" toes—i.e., those associated with pes cavus and boot-caused deformities—attention is directed chiefly to the extension of the metatarso-phalangeal joints rather than to the flexion of the distal joints. In pes cavus the toes are dealt with after the arch has been flattened sufficiently by the Steindler operation. The various procedures for correcting the toes are: (1) Division of dorsal extensor tendons and capsules, and tethering the toes down to a slotted and looped sole-plate for four to six weeks, by night and day, followed by active and passive exercises and electrical stimulation of the intrinsic muscles. This is the older method, and is liable to result in relapse after some months. (2) Transplanting the dorsal extensor tendons into the necks of one or more metatarsals or into the dorsum of the foot. There are several modifications of this method. (3) Transplantation of the long flexor tendons from the terminal to the proximal phalanges, a method first advocated by the writer. The hyper-extension at the metatarso-phalangeal joints is corrected by one or other of these methods, while the flexion of the toe-joints is overcome by passive stretchings and active exercises, perhaps assisted by tenotomy of the flexor tendons. In deformed toes associated with hallux valgus the excision and tenotomy methods as described for real hammer-toe may be carried out on those toes which are causing painful disability.

In retentive splintage after correction, when the toes need to be held flexed in the metatarso-phalangeal and extended in the more distal joints, the sealed dressing and looped sole-plate methods described above are more practicable than the use of plaster-of-Paris in which it is difficult to obtain precise correction without risk of producing pressure sores.

W. H. TRETHOWAN, F.R.C.S. Eng.,
Orthopædic Surgeon to Guy's Hospital.

Special Articles.

THE MILK-SUPPLY AND ITS IMPROVEMENT.

BY WILLIAM G. SAVAGE, B.SC., M.D. LOND.,
COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

III.*—REMEDIES TO IMPROVE THE MILK-SUPPLY.

THE final report, issued in 1919, of the Committee on the Production and Distribution of Milk, emphasised what all authorities on the subject are agreed upon, that the present milk-supply is highly unsatisfactory. Since that date the only Act passed affecting milk has been the Milk and Dairies (Amendment) Act, 1922, which in most essentials leaves the problem alone. In addition to questions of chemical purity, which cannot be dealt with from limits of space, there are three different bacteriological problems—i.e., freedom from tubercle bacilli, general bacterial cleanliness, and removal of the liability to spread acute infectious disease. With so many problems it will be obvious that there can be no simple short cut to a satisfactory supply, but that it is a problem which must be surveyed from many angles.

More Effective Legal Control.

The need for additional legal powers has been demonstrated in the previous article. There is, however, another Act upon the Statute-book, the Milk and Dairies (Consolidation) Act, 1915. This is a unique measure, since (with some modifications) it is a repetition of and substitution for the Milk and Dairies Act, 1914, which, although passed, never came into force, and, like it, the 1915 Act has been postponed and has never come into operation. The 1922 Act further extended its date of coming into force to Sept. 1st, 1925. This Act has been kept in cold storage for ten years, and there is nothing to prevent a further Act from still further extending the period of hibernation.

From the point of view of the milk-reformer this Act cannot be accepted as likely to solve all the existing milk deficiencies. On the other hand, it contains a number of valuable and important sections. The mother Bill was in the end an "agreed" measure. An "agreed" Bill in the sphere of public health usually means that to get it passed many of the best clauses have either to be withdrawn or accepted handicapped with "safeguards" which make them unworkable or so slow in operation that they fail to do much good. It is cumbersome in working, since it gives both the smaller local authorities and county councils powers which are in part concurrent. Its chief value is in Section I. which gives the Ministry of Health power to make Orders which, if fully made use of, would go a long way legally to ensure clean milk. These powers are coupled with the "safeguard" that they have to be made with the concurrence of the Board of Agriculture and Fisheries. These powers are, therefore, very much in the nature of a dark horse of possibilities but hardly a certainty, perhaps not a starter. The need for a new Milk and Dairies Order to control method in milk production has been amply demonstrated in my last article, and under Section I. of the 1915 Act an effective Order is possible. The Draft Milk and Dairies Order, 1915, proposed to be made under the Act was very valuable, and it is to be hoped that any Order issued will be along the lines of this Order, with additions dealing with methods of clean milk production.

While education is more important than legislation in connexion with an improved milk-supply, more definite legal requirements as regards milk production and handling are in themselves of great educative influence when tactfully carried out. No experienced milk-reformer wants drastic enactments, and the essentials are very simple things. Too zealous workers have done much harm, and led agricultural interests to take fright at what are to them, and indeed in reality, impossible requirements. If, however, it is right to require cows' udders to be clean and milkers to have clean hands and to milk in cleanly fashion, and for churns to be sent locked, why not say so legally and have done with it? There is no dispute as to the essentials.

In my opinion it is for the medical profession to press for better control, either by the passing of a suitable Milk Act or, failing that, by no further postponement of the operation of the 1915 Act. It is impracticable to discuss all the sections of this Act, but as regards tuberculosis they demand a little more consideration.

The Prevention of Human Tuberculosis from Milk.

Everyone who has made a study of the problem of the eradication of bovine tuberculosis is aware of its extreme complexity and difficulty, in part due to its magnitude, in part to the large financial interests involved, in part to the fact that it concerns two Government departments looking at the problem from different angles. Fortunately it is equally obvious that it is a solvable problem, while it is agreed that progress can be achieved along several lines. It is an agricultural even more than a public health question, and while the two are not identical they are interdependent. It is impracticable to discuss these lines of progress and remedies in detail here, and, indeed, they would involve a very large number of purely technical considerations. Fortunately there are many valuable papers available on the subject.

Just as with human tuberculosis, it is obvious that drastic measures are impracticable and would defeat their object, and that progress can only result by advancing along definite and approved lines. The two most approved lines have been (*a*) the thorough separation of healthy from tuberculous animals and the rearing of a healthy non-infected herd; (*b*) the elimination of cases of "open" tuberculosis in bovines as the cases which most spread the disease and mainly infect the milk-supply.

Experience has shown that much can be effected along these lines. Judging from past legislation the most probable lines of administrative action will be a re-enactment of the 1914 Tuberculosis Order, together with the tuberculosis clauses of the 1915 Act. These clauses in the 1915 Act, if they become effective, will give a good deal of power, but they seem complicated in working and, while they may prevent some infection from tuberculous milk, will do little to reduce the amount of bovine tuberculosis. Their greatest hope in this direction is in the power they give for the appointment of whole-time veterinary inspectors and for bacteriological examinations. The Tuberculosis Order of 1914 is an Order of the Board of Agriculture which was suspended at the onset of the war and has not been re-enacted. In the words of the covering circular, the Order "aims at securing the destruction of every cow found to be suffering from tuberculosis of the udder, or to be giving tuberculous milk, as well as of bovine animals which are suffering from tuberculosis with emaciation." In other words, it follows line (*b*) mentioned above. To detect these animals reliance was placed upon notification by their owners to the local authority (the authority under the Diseases of Animals Act, 1894) and also on notification from veterinary surgeons in the course of their practices. Compensation was paid for these animals when slaughtered on an approved scale, so the cost was heavy.

---

* Parts I. and II. appeared in THE LANCET of May 23rd and 30th and June 6th respectively.

Since many writers—veterinary and others—are pressing for the re-enactment of this Order, presumably along the original lines, it is of some importance to consider whether it is useful from the public health point of view. In theory the Order should be a potent weapon to reduce tubercle bacilli in milk, and reduce the amount of bovine tuberculosis. As operated, however, my experience and inquiries were that it was doing but little along these directions. My primary objection is that it was not being used as a preventive measure, although this may be true in some cases, but as an agricultural measure to pay compensation for these special tuberculous animals. Unless worked on preventive lines in the great majority of instances the cases of udder tuberculosis and "wasters" will not be detected and slaughtered until *after* they have been actively excreting tubercle bacilli for long periods. No compensation should be payable for any animal if the conditions could reasonably have been detected at an earlier stage. Two postulates are, I think, essential. First, that it must not be run by the County Agricultural Committee as a purely agricultural measure without any coöperation with the public health authorities (this was the way it was worked in Somerset), but must be looked at and worked as a preventive measure. Secondly, the veterinary inspectors who visit, examine, and report must be *whole-time* officers of the authority working along preventive lines and either under, or closely coöperating with, the Public Health Committee. Unless these two postulates are fulfilled the compensation under the Order is, in my opinion, largely wasted, as it will neither reduce the amount of bovine tuberculosis nor diminish the infectivity of the milk-supply.

While the precise lines of advance are a matter for the experts to decide, it is for medical opinion to enunciate that the present position is a reproach to public health and an economic disaster to the country.

Universal Controlled Pasteurisation.

It was pointed out in Article I. that the term pasteurisation covers different processes and that ordinary uncontrolled pasteurisation cannot be relied upon to do anything beyond prolong the life of a bacterially contaminated milk. On the other hand, a definite case can be made out for adopting a system of scientifically controlled pasteurisation as the best means of securing a safe milk-supply. When the arguments in favour are dissected they amount to three: (*a*) The difficulties in the way of preventing the contamination of milk with pathogenic organisms are very great, and even the best safeguards are but partial. Complete safety can only be attained by submitting the milk at a stage before distribution to treatment by heat adequate to ensure the death of any pathogenic bacilli possibly present. (*b*) Properly carried out such treatment does nothing to damage the nutritive or vital properties of the milk. (*c*) Pasteurisation is much cheaper than a system of efficient dairy inspection. While the last is agreed upon by all, upon the first two points there is by no means unanimity.

Objections to such a scheme of universal pasteurisation of milk are three-fold. In the first place, many scientific observers do not acquiesce in the view that efficient pasteurisation does not damage the milk. In the second place, its success depends upon efficient working, and in work-a-day practice it may fail lamentably. The apparatus and connecting pipes may not be kept clean and may add bacteria, the machinery may break down or be improperly used. If relied upon as the sole safeguard it may fail us, and I have studied several outbreaks of food poisoning due to milk, in which the outbreak was directly associated with the use of milk which was supposed to have been pasteurised, but which for trade reasons had not been so treated. The danger of inefficient pasteurisation is a real one if other than clean milk is allowed to be pasteurised, since the operator knows that highly contaminated milk may be damaged by heat, and his bias is to underpasteurise. In the third place, we have to realise that as adopted in this country it is a substitute for cleanliness. Its advocates deny this and talk about it as a temporary measure which will in no way retard progress to obtain a cleaner milk. This is an attitude with which I find it impossible to concur. There is no need to pasteurise clean milk to enable it to be delivered to long-distance customers, a fact which has been repeatedly demonstrated. It did not become adopted in England as a public health measure but as a trade process to enable bacterially contaminated milk to be conveyed unsoured to the consumer, and its further extension will continue the process. It costs money to pasteurise, and the wholesale distributors are not going to pay this and also pay more to get clean milk. It is true that milk on the verge of going sour cannot be pasteurised, but milk containing a million or so of bacteria per c.cm. is being pasteurised every day.

To my mind the advocates of pasteurisation spoil their case by overstating it. A really strong case can be made out for universal pasteurisation on the lines that the difficulties and expense of obtaining a pure safe milk are too great, and that it is cheaper and equally satisfactory to obtain it fresh and therefore not excessively contaminated, and pasteurise it under strictly defined and rigidly controlled conditions—such milk to be labelled as pasteurised, re-heating forbidden, and all other than scientifically controlled pasteurisation methods prohibited. All milk sold as fresh milk not to have been subjected to any treatment. The balance of scientific evidence is favourable to the view that it is possible to select time and temperature conditions that will not damage the milk on the one hand, and yet will destroy with reasonable reliability non-sporing pathogenic bacilli. Such a contention is a confession of failure, in that it says in effect that we cannot apply to milk what we apply to other foods, but it is a perfectly logical one, and it is arguable that it is the best solution of a difficult problem. Unfortunately, pasteurisation is never presented in this form, but always with promises of benefits which it is unable to perform and without safeguards which it is necessary to provide.

In some parts of the U.S.A. it is worked in connexion with adequate measures for controlling the purity of the supply at the source, bottling under controlled conditions and supervision throughout.[1] That, again, is logical, but is not the way it is advocated in England. We are very far indeed in this country from any system of adequate supervision over production together with controlled pasteurisation, and anything less is unsafe and inexpedient.

---

[1] As an interesting corollary to these remarks I notice that Dr. C. J. Hastings at the World's Dairy Congress, 1923, talked about the objection to pasteurisation as being for the most part a pitiful exposition of ignorance, but he then went on to describe as a matter of course a complete inspection system, bacteriological examinations, and the summary rejection of all dirty or below standard milk. In this country the advocates of pasteurisation do not couple all this together.

(*To be concluded.*)

BRISTOL HOMŒOPATHIC HOSPITAL.—Princess Helena Victoria recently opened this hospital, the gift of Mr. W. Melville Wills, in memory of his son, Captain Bruce Melville Wills, R.E., who was killed in the war. The whole of the wards face to the south and each ward has a sun balcony; a system of floor warming has been installed which obviates the necessity for radiators and leaves the wards unobstructed. The hospital has been under construction since 1921, when the Prince of Wales laid the foundation-stone.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

EVIDENCE OF THE BRITISH MEDICAL ASSOCIATION

(continued from p. 1250).

The Right to Admission to the Panel.

(Q. 15214.) The witnesses said that they would strongly oppose any limitation on the right of a registered practitioner to enter the insurance service, whether the present general practitioner service or the proposed extended service of consultants and specialists (assuming in the latter group that the doctor had the necessary status). Dr. Cox said that the statement made by a previous witness before the Commission that the Association had agreed to such a limitation was wrong and must have been made under a misapprehension.

Regulations.

(Q. 15216–20.) With regard to the suggestion in the evidence that complaints should in the first instance be submitted to the chairman of the local medical committee and the chief administrative medical officer of the area, it was asked whether this would not place the decision of these questions too much in the hands of the profession, and whether some lay element was not desirable. Dr. Brackenbury said that if questions of behaviour as between doctor and patient were eliminated from the complaints procedure and regarded as covered by the freedom which now exists for the doctor or patient to terminate the relationship at any moment, the inclusion of a lay element, even in the court of first instance, would not be objectionable.

Dr. Bolam said, with regard to regulations generally:—

> (Q. 15216.) The profession as a whole feels very strongly (and in particular those outside the Insurance Scheme at present feel that if they are to participate in it at any future time) that it is necessary that any regulations shall only be in regard to administrative procedure and the arrangement of it, and not anything which would interfere with the mode of treatment given by the doctor or the relationship between the doctor and patient in a medical sense.

There had been a tendency on the part of the Ministry of Health recently to interpret the regulations in a manner which gave rise to apprehensions. On another aspect, Dr. Brackenbury said:—

> (Q. 15220.) Where the machinery agreed upon for judicial inquiries has been complied with—where the Insurance Committee has adopted one particular decision—it seems to us entirely improper that the court of appeal—the Ministry—should step in and write a letter to that Insurance Committee suggesting they should alter the charge and proceed differently.

Medical Institutions.

(Q. 15221–15296.) With regard to medical aid societies and other approved institutions, Dr. Cox explained that it was not so much the fact of payment by salary which was objected to as the control of a lay committee. He said:—

> I do not know of any lay committee which has the employment of medical men, with so little sense of real public responsibility as the committees of these particular services. It is a very different thing for a medical man to be employed by a public authority—a responsible public body—and to be employed by a body connected with one of these institutions, the calibre of which cannot be at all the same, and over which there is nothing like the same amount of public check. We are against these institutions because we know they do not get the quality of medical men which is prevalent in the ordinary panel system.

As regards the institutions in the colliery areas of South Wales, he said:—

> I have no hesitation in saying that there their influence has been very detrimental indeed to the medical service given to the public in those areas. For nearly 30 years—long before the Insurance Act came in—we have been fighting these institutions, because they proceeded on what we thought were entirely wrong lines, the theory being that the miner, who is, of course, a very politically-minded person and who believes that he is able to manage services of all kinds, thought that he could manage the doctor. They deliberately adopted the idea of the employment of a doctor as a whole-time servant, who should be the doctor of the committee and not the doctor of the individual person, which we think is wrong; it is fundamentally against the provisions of a good medical service.

The Proposed New Authority.

(Q. 15297–309.) The Association suggested that cash benefits should be separated from treatment benefits and the latter administered by a new authority which would control also all other health services. The profession would be satisfied that the new authority should be a statutory committee of the county council or county borough council, though these would not be always in their present form the best areas for the purpose.

> (Q. 15299.) The proposal, then, would mean the disappearance of the Insurance Committee and the unification under the new authority of the medical services at present administered by the Insurance Committee, the public health authority, the Poor-law guardians, and the education authority. As chief officer of the new authority you would have an administrative medical officer of high standing both in medical knowledge and in administrative work, who I suppose would be a salaried officer?—Yes.

Dr. Brackenbury pointed out, however, that they did not contemplate this engagement of salaried officers for treatment purposes at all, except for a limited period of time for tuberculosis and venereal disease services and for infectious diseases hospitals. Their general view was that:—

> (Q. 15300.) The actual treatment work as distinguished from administration, or we may even say inspectorial work, would be done by part-time officers either on the insurance system for domiciliary attendance or on the sessional system for the treatment clinics. The necessity for many of the treatment clinics will be done away with by the provision of the family doctor for the dependants of the insured person.

(Q. 15305.) As regards the financing of the enlarged health service, the funds would be derived, it was thought, from the same sources as at present, but not all pooled. The income from the insurance scheme would be preserved as a separate fund, the new authority receiving a capitation payment in the same way as the insurance committees do at present.

The general scope of the extended scheme proposed by the Association would be found not inconsistent with the main lines of the proposals of the Consultative Council to the Minister of Health in 1920, but corresponded rather more closely to the Scottish than to the English report.

Certificates of Incapacity.

(Q. 15310–11.) The words "incapable of work" on the certificates gave rise to much difficulty, and the words "unfit for your work" would be more suitable, with a provision that when the Approved

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

Society felt that the question properly arose, the doctor could be asked, "Is he unfit, not for the particular work, but for any work?"

The Rural Practitioner.

(Q. 15326–35.) Dr. J. P. Williams-Freeman gave evidence as to the disadvantages from which the rural practitioner suffered. He suggested that there should be the same general capitation fee for all practitioners alike throughout the country, but that in certain sparsely-populated districts this should be augmented so as to raise the amount of money paid for insured persons to a proper proportion, "which is generally taken to be one-third of what ought to be a reasonable remuneration for an educated medical man."

The witness agreed that a great part of the country district is now within the scope of operations of town doctors owing to the coming of the motor-car, but said that a certain amount of village practice ought to be kept going, because he believed this to be necessary for the population. Dr. Williams-Freeman outlined the way in which a specialist service could be provided for rural areas on a market town basis by means of ambulances and clinics.

EVIDENCE OF OTHER MEDICAL BODIES.

The Medical Practitioners' Union.

(App. XLVIII.; Q. 15337–744.)

Evidence was given by Dr. E. A. Gregg, President; Dr. Gordon Ward, Vice-President; Dr. A. Welply, Secretary; and Mr. Charles Davis and Mr. S. G. Davis, solicitors.

The Medical Practitioners' Union has between 3000 and 4000 members, and claims to represent the more progressive opinion of all sections of the profession. It suggests that its expressed opinions are such as can be translated into legislative action within a reasonable period, basing this claim not so much on the favourable reception of its draft statement of evidence by the profession as on its knowledge of professional ways of thought and of the past relationships between the State and medical men.

A State Medical Service.

The evidence emphasises the importance of maintaining the advantages of private practice, and suggests that it is right and proper that the provision of medical services by the State should extend until the widest possible benefits of preventive and curative medicine are available for those persons who without State assistance would be unable to obtain them. Those to whom benefits might usefully be extended comprised a very large proportion of the community, and the most economical and satisfactory way of financing such an extended service might be by abandoning individual contributions in favour of direct provision from the National Exchequer. The Union is sceptical as to the alleged educative and moral value of the insurance elements in the existing scheme.

The Disappearance of Approved Societies.

The Union is of opinion that the system of Approved Society administration has proved unsatisfactory and that the Approved Societies as such should no longer be continued, and accordingly suggests: (1) That all extra cash benefits should be abolished as from a certain date and all surpluses should from that date be held by the State on behalf of contributors; (2) that insured persons should be transferred from societies to county committees; (3) that the old age pensions and unemployment benefit machinery should be amalgamated with that part of the county committees' work which dealt with sickness benefit; and (4) that five years hence there might be an extension of medical benefit to a larger community.

The Ministry of Health Condemned.

A lengthy statement is embodied in the evidence in support of the following condemnation of the Ministry:—

> It is the deliberate and considered opinion of the Union that a great State department, the Ministry of Health, has shown itself to be incapable of appreciating or unwilling to act upon those elementary principles of justice which have made our courts of justice the pride of all English-speaking peoples.

As regards the whole of the complaints and appeals machinery, it is claimed that:—

> The delay and denial of justice is so gross and deliberate and the elementary rights and liberties of the individual are held in such low esteem that insurance practitioners are justified in demanding, as they do demand, that the whole system shall be swept utterly away.

Other Recommendations.

The evidence also embodies proposals for reconstruction of the system of certification which, it is said, is even more burdensome than record-keeping as at present required, both being a menace to the therapeutic success of the system. It is also contended that the methods by which the views of insurance practitioners are ascertained and presented, whether to the Ministry of Health or before the Royal Commission, are in many respects unsatisfactory and call for reform, and that the previous negotiations in regard to remuneration have been unsatisfactory. A new basis for calculating and increasing the remuneration of panel doctors is proposed.

With regard to maternity service, it is suggested that National Health Insurance funds could be most profitably employed by means of grants to local authorities, voluntary hospitals, and district nursing associations.

(To be continued.)

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1924 of a group of two county boroughs and four boroughs:—

Name of district.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Blackburn C.B.	127,640	15·5	14·2	0·87	1·4	4·1	30	84	5·0
Ipswich C.B. ..	82,710	17·3	9·7	0·97	1·4	1·8	—	52	2·8
Ealing B. ..	68,370	14·3	11·1	0·75	1·4	2·1	23	47	5·1
Macclesfield B.	32,886	17·0	13·2	0·90	1·9	1·8	32	85	1·8
Shrewsbury B.	31,660	19·4	11·9	1·20	1·3	3·2	22	46	4·8
Margate B. ..	28,380	14·6	11·2	1·02	1·7	1·7	—	39	0·0

C.B. = County Borough. B. = Borough.

Blackburn.

Dr. W. Allen Daley, in his fifth and valedictory report for Blackburn, indicates the progressive attitude adopted by his health committee towards public health matters by recounting some of the measures which have been adopted during his five years of office. An antenatal clinic was established in 1921, and during 1924 293 expectant mothers made 700 attendances. A six-bed maternity hospital was established in August, 1921, to which 122 cases were admitted in 1924. Three new child welfare centres have been established with attendances numbering 20,241 in 1924. The work of the V.D. centre has been associated with the child welfare department by placing the woman medical officer for child welfare in charge of the treatment centres for women and children. District nurses attend home-treated cases of measles, whooping-cough, ophthalmia neonatorum, tuberculosis, diarrhœa, and other diseases sent to them by the health committee. A band of 60 voluntary workers, mostly British Red Cross, do excellent work in assisting at the child welfare centres. In February, 1923, an X ray apparatus was purchased for the tuberculosis dispensary and pneumothorax treatment was begun. A sanatorium school for pre-tuberculous children and a scheme for the prevention and treatment of crippling were put into operation during the same year. New lairage accommodation has been provided at the public abattoir and the number of private slaughter-houses has been reduced from ten at the end of the war to two in 1924. The farms in the borough have been modernised. "Certified" milk has been on sale since 1921 and the demand for it is constantly increasing. "Grade A" milk is obtainable from three farms and the demand exceeds the supply. Three "clean milk" competitions have been held. A covered milk container with a tap at the bottom has been devised and is in use in milk sale shops. Parliamentary powers have been obtained for the registration of premises where meat food products are prepared. A scheme has been adopted for improving the welfare of the blind by assisting the workers at the workshops of the blind and coöperating with the society for visiting the blind. In 1920 there were 9329 privies and pail-closets; all of these, except 174 in the suburbs of the town, have been converted into the ordinary water-closet. A scheme is now in operation for the substitution of galvanised-iron bins for ashpits. Attention has been paid to the hygienic condition of cinemas and other places of entertainment. A comprehensive scheme for educating the general public on how to maintain their health has been in operation since the end of 1920. In connexion with this there have been exhibitions, many cinema and other lectures, health poster competitions, newspaper articles, health sermons, and other activities. One is not surprised that Dr. Daley congratulates his health committee and council on their policy.

Ipswich.

Dr. A. M. N. Pringle gives some particulars of the behaviour of the tuberculosis death-rate in Ipswich. From 1841 to 1870 the female death-rate from pulmonary tuberculosis exceeded the male, but from that time onwards it has been consistently and considerably lower. During 1921 and 1922 there was little difference between the two rates, but during 1923 and 1924 the female rate has only been two-thirds of the male. From 1840 up to the present time there has been very little difference between the male and female rates from non-pulmonary tuberculosis in Ipswich. The rate for cancer reached its highest recorded point in 1924, the male rate being 1·48 and the female 1·36. Another table shows the decline in infant mortality. From 1840 to 1870 the infant mortality-rate in Ipswich averaged about 170; from 1870 to 1900 it averaged about 150; during the three years 1922–24 it has averaged 52. A remarkable feature of the rate during 1924 was that there were no deaths of illegitimate children. The recorded births of illegitimate children numbered 64. Dr. Pringle points out that since 1915 diarrhœa has been "wiped out" as a serious factor in the production of infant mortality. The very high case-fatality of puerperal fever shows that all the cases are not being notified, and Dr. Pringle suggests the advisability of having all cases of puerperal pyrexia of 100·4° F. or over (maintained for 24 hours) notified. There is ample hospital accommodation for all cases of puerperal fever either in the East Suffolk Hospital or in the isolation hospital.

Ealing.

Dr. Thomas Orr reports that all the 14 midwives practising hold the certificate of the Central Midwives Board. The midwives are under the supervision of the county council, but they frequently refer cases to the borough maternity and child welfare centre. About 180 maternity cases from Ealing were admitted to the Chiswick and Ealing Maternity Hospital during the year and the contributions made by these patients amounted to £819 17*s.* 6*d.* Eighteen licences were granted to one milk company to sell "pasteurised" milk at their various premises; 19 licences were granted (18 to one company) to sell "Certified" milk; and one licence to sell "Grade A (tuberculin-tested)" milk. The housing difficulties still remain acute. Twenty-eight flats erected by the town council provided for some of the most urgent cases. In his school report Dr. Orr points out that the erection of the Grange School marks a recent development of school construction. In 1905 the schools built had a central hall with classrooms round it. The next development was a central hall with one outside wall and the classrooms arranged round the other three sides. The Grange School is a single range of classrooms in the form of the letter E with the central arm left out. Along the inner side of the building is a broad corridor with a glass roof and on to this corridor the whole of the classrooms open in such a manner as to form when required an open-air school. The two centre classrooms, by the folding of a glass and wood partition, can be converted into a large assembly hall. Dr. Orr states that the head teachers use every opportunity to teach in the open air when weather permits, and he regards the new Grange School as a noteworthy step in furthering open-air education.

Macclesfield.

Dr. J. Hedley Marsh mentions that there were nine notifications of encephalitis lethargica from February to August with three female deaths at ages 8, 13, and 71 respectively. A circular was issued during the year to all milk producers on the production of clean milk, based on an article by Mr. A. T. R. Mattick, of the Reading Institute. The report contains a large number of analyses of the town's water, many of which are not altogether satisfactory. A new impounding reservoir with a capacity of 134 million gallons has been begun.

Shrewsbury.

Dr. H. Gordon Smith makes his fifth and last report before taking over his duties at Lincoln. Shrewsbury has a dual water-supply. The drinking water is obtained from a deep well about two miles outside the borough, is pumped into a reservoir, and reaches the town by gravitation. It is supplied to the inhabitants by means of standpipes in the streets. The river water is laid on to the houses, but is not intended for drinking purposes. To minimise risk, however, this river water is chlorinated and filtered through Bell's pressure filters. Six cases of encephalitis lethargica were recorded, four being fatal. Dr. Smith claims that probably no other town of similar size to Shrewsbury has tackled the housing problem so seriously and so successfully. During 1924 107 houses were erected with State assistance, 54 by the local authority and 53 by private enterprise. The lessening of pressure actually enabled eight insanitary houses to be closed during the year.

Margate.

Dr. Rowan McCombe mentions that the question of public baths has been much discussed by the health committee and the Ministry. In the older parts of the town not only cottages, but many of the better-class houses have no bathroom. The need is for a simple type of building for the use of the occupants of the bathless houses. There are already swimming baths owned by a private firm. Margate is still faced with a deplorable shortage of houses. The council erected 84 houses in 1921, 52 in 1922, 22 in 1923, and none in 1924. A further 48 houses were, however, begun in 1924. Owing to the growth of the town it has been found necessary to devise means for dealing with the increased sewage and storm water. The scheme, which has received the approval of the Ministry, includes deep-level sewers, large main sewers, pumping stations, pumping engines, and storm overflow drains. Margate came out well in the matter of hours of sunshine in 1924 with 1827·2 hours, as compared with 1725·3 in 1923.

SCHOOL MEDICAL SERVICE.

‡ Secondary schools, 17·6 per cent.
‖ Excluding dental defects and uncleanliness.

Warwickshire.

The concise and numbered paragraphs in which the report on the school work is presented by Dr. A. Hamilton Wood makes for brevity and easy reference, but leaves the reader wishing that observations had been made on points of interest arising in the course of the work. No special inquiries or investigations have apparently been undertaken. The satisfactory method of employing the health visitors as school nurses is in force—satisfactory in that it helps to coördinate the various health services, prevents overlapping, and is a strong link in the chain of preventive medicine between the parents and the medical services generally. A full tabular statement is appended of the work individually carried out by the school nurses.

The percentage of defects in the secondary schools is greater than that found in the elementary schools, but this is more apparent than real, and is largely due to the inclusion of dental defects in the return for secondary schools. As has been found elsewhere, treatment is more difficult to obtain so far as tonsils and adenoids are concerned, as only 22 per cent. of secondary scholars obtained treatment as against 55·9 per cent. of elementary children. No school meals have been provided as "there has been less unemployment in the industrial areas as compared with two years ago." No mention is made of open-air classes or schools, though even in rural districts such classes have their advantages, and some such provision would seem to be indicated for the 30 cases of malnutrition referred for treatment, of whom only eight appear to have been treated at the clinic. We trust the education committee will see the necessity of making suitable provision for the treatment of crippling defects. Dr. Wood reports on the requirements of such a scheme which would deal with over 200 children known to be so suffering.

Apparently the committee are now considering the question of providing suitable educational facilities for the 164 feeble-minded children, of whom 100 are at present in elementary schools and 64 are only suitable for special school treatment, and we hope with Dr. Wood that such provision will speedily materialise.

Holland County Council (Lincoln).

Dr. H. C. Jennings's report has been compiled with great care and has many points of general as well as technical interest. We note that the school nurses are also health visitors and tuberculosis nurses and give only two-fifths of their time to the school medical service. Comment is made on the school sanitation, and attention is drawn to the following points: (*a*) the discontinuance of the use of antiquated types of desks; (*b*) the abolition of all privy vaults; and (*c*) the provision of sufficient playground space, such space to have a hard, smooth, and impervious surface. It seems appalling in these days to think of children using a road as their playground, especially as the speed of motor-cars and their numbers are rapidly increasing.

At present there is no provision for the treatment of dental defects, and it is to be hoped that the scheme laid out in the report will be speedily adopted. There are comprehensive details on the cost of dental treatment. As the cost would entail 1/4th + 1/10th of a penny charge on the rates, and this includes the provision of a mobile dental outfit, one wonders why it has not been in being long ere this. Dr. Jennings's notes on diet of school-children are of interest, and he urges that elementary dietetics should find a place in the school curriculum. We might also add propaganda amongst parents. No facilities exist for the provision of school meals and there are no open-air, physically defective, nor mentally defective schools in the area.

There were a great number of school closures, and in view of the memorandum on "Closure of and Exclusion from School" issued by the Ministry of Health and the Board of Education, 1925, they would appear to be excessive, notwithstanding that this is a rural area.

Bedfordshire.

The percentage of defects found is close to the average for the whole country. The proportion of parents present at routine examinations was high—65·7 per cent. Dr. R. T. Herdman comments on the great value of this factor, "For five minutes talk with a mother about the health of her child has a far greater effect than any number of letters advising her what should be done," although it takes longer to examine a child when one has at the same time to point out to the parent any defect found and explain its effect on the health of the child. In this connexion it should be noted that the whole of the medical inspection is carried out by the school medical officer himself, so that the scope of his activities is more limited than he would no doubt desire.

The arrangements for treatment are not detailed, but the percentage of all defects treated, excluding verminous conditions, is good—72·21 per cent. Spectacles were supplied in 71 per cent., though it is remarked that in agricultural occupations glasses are not always felt to be as essential as in urban employment. There are a considerable number of children suitable for special education—viz., 103 mental defectives and 31 physical defectives—still in elementary schools or receiving no education at all, and though in these scattered rural areas special provision is manifestly difficult, yet we would hope that something more may be done in the near future. The dental work is evidently carried out under some difficulties which would be greatly lessened by the establishment of central clinics.

Reading between the lines of the whole report, we get the impression of a task carried out with scarcely adequate facilities in a very human and sympathetic spirit.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 6TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 99; scarlet fever, 1293; diphtheria, 678; enteric fever, 51; pneumonia, 695; puerperal fever, 37; cerebro-spinal fever, 6; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 66; dysentery, 5; ophthalmia neonatorum, 105. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed an increase of 11 over the number for the preceding week.

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever, 62 from measles, 16 from scarlet fever, 62 from whooping-cough, 32 from diphtheria, and 42 from influenza. In London itself the deaths from influenza numbered 7, from whooping-cough 9, and from diphtheria 10.

WORKSOP VICTORIA HOSPITAL.—A new wing of this hospital, which is part of the war memorial scheme, was opened by Sir John Robinson on May 30th. The extension cost £15,000.

THE OSLER MEMORIAL AT OXFORD.

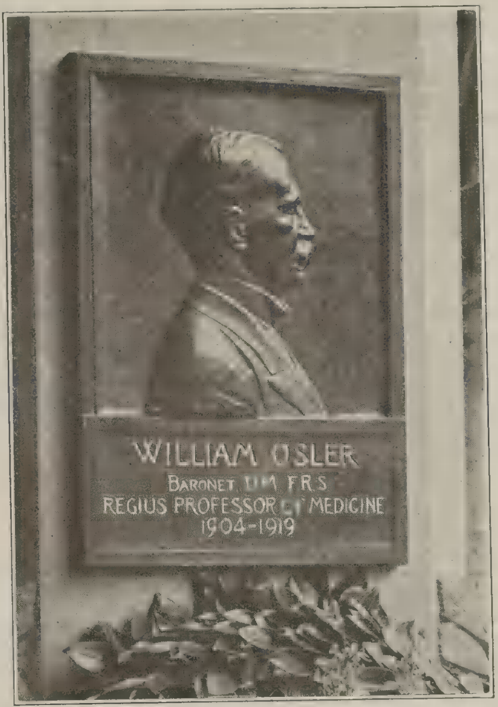
A BRONZE plaque in memory of Sir William Osler, late Regius Professor of Medicine, was accepted on behalf of the University and unveiled by the Vice-Chancellor, Mr. Joseph Wells, Warden of Wadham, on June 10th, in the Court of the University Museum, in the presence of a large and representative gathering. Among those present were Lady Osler; Sir Charles Sherrington, President of the Royal Society; Sir Archibald Garrod, Regius Professor of Medicine in the University of Oxford; Sir Humphry Rolleston, President of the Royal College of Physicians, and Regius Professor of Physic in the University of Cambridge; Dr. J. G. Adami, Vice-Chancellor of the University of Liverpool (representing McGill University); General Sir William Leishman, Director-General, Army Medical Service; the Master of University, the President of Corpus and Mrs. Allen, the President of Magdalen and Lady Warren, the Dean of Christchurch, Dr. Ainley Walker, Dean of the Medical Faculty, Prof. E. B. Poulton, and Prof. Arthur Thomson. The plaque, which has been affixed in the University Museum by permission of the delegates, is the work of Mons. F. Vernon, a French sculptor, and is a replica of that made for the Faculty of Medicine of Maryland, U.S.A. It was presented to the University on behalf of the subscribers to the Sir William Osler Memorial Fund by the President of Magdalen.

Sir Herbert Warren spoke in terms of much warmth and feeling of the services of Sir William Osler to Oxford and to medicine, and of the charm and inspiration of his personality. He referred briefly to the remarkable growth and development of the School of Medicine and its scientific departments, since the time when Sir Henry Acland set to work to devote himself to the restoration of an almost derelict school. By their genius and enthusiasm he, and his successor, Sir John Burdon-Sanderson, infused new life into the school and launched it on the fresh career of usefulness to which the late Regius professor so largely contributed.

The Vice-Chancellor, in unveiling the beautiful plaque, said it was a very great personal pleasure and honour to him to accept the memorial on behalf of the University. There were many who knew Sir William Osler as a name of authority in medicine; but here he was remembered even more for his never-failing kindness, his sympathy, his love of children, and his magnetic personality. He was not only a great man, but a most lovable one. It was very fitting that his memorial should stand in a place connected with so many great men of Oxford, and especially of Christ Church, his own college.

A wreath of laurel and white heather was then placed at the foot of the memorial by Mr. J. F. Fulton, Magdalen and Harvard, on behalf of the Inter-State Post-Graduate Assembly of American Physicians and Surgeons.

Sir Humphry Rolleston paid an eloquent tribute to Sir William Osler's life and work which adorned so many departments of learning: "Osler's services to medicine, like the man himself," said Sir Humphry Rolleston, "were remarkable for their infinite variety; his activities were not mainly confined, as have been those of some heroes of our profession, to one field, such as laboratory research, clinical observation, teaching, or education; he played a prominent part in all these spheres. Osler first made his mark as a microscopist—in an investigation of the Canadian Diatomaceæ, then of the blood platelets, and somewhat later of the malarial parasite; and as a morbid anatomist at McGill, Montreal, he laid the firm foundations of that sense of proportion so essential for a physician. As a clinician he established new syndromes, such as erythræmia (Vaquez-Osler disease), hereditary telangiectases, splenic anæmia, and pointed out certain symptoms or signs in recognised diseases, so that 'Osler's nodes' in subacute bacterial endocarditis are familiar. The most modern methods of the laboratory were fully utilised to supplement the routine and thorough examination of the patient, the new and the old being skilfully blended so as to obtain the best of both. Like Trousseau, he ranged widely over the whole field of medicine and enriched it both by observation and by deductions based on collected statistics; his literary output in 49 years amounted to more than 770 books, papers, and addresses." Sir Humphry Rolleston dwelt on Osler's inspiring influence, owing to his perpetual youth in mind and wide sympathy and knowledge of young men, teaching them not medicine only, but humanity and the way of life. "Ever active in the wards," the speaker continued, "Osler's influence stimulated others to individual observation and research and so to advance the science and art of healing. His writings, especially his great text-book, remarkable alike for its conciseness, completeness, and atmosphere of personal experience, brought him numberless followers whom he had never met. A happy manner of persuasive enthusiasm admirably fitted him as a great leader in campaigns for the prevention of diseases, such as enteric fever, malaria, tuberculosis, and venereal infection, and he not only originated, but carried through successfully schemes for the benefit of the nations. His most remarkable success, however, was as an educator of the medical profession; this was largely due to his personality and to the way he put into effect his motto 'Write me as one that loves his fellow men.' A great believer in the educational and harmonising influence of medical societies and in united effort, he was the moving spirit in starting the Association of Physicians of Great Britain and Ireland, and for its first 12 years the senior editor of its official organ."



Sir Archibald Garrod proposed a vote of thanks to the Vice-Chancellor for presiding on the occasion, and referred to the position happily chosen for the memorial in close proximity to the statue of Sydenham and near the figures of Harvey, Hunter, Acland, and Burdon-Sanderson.

THE OSLER MEMORIAL FUND.

By a recent Decree in Convocation the University of Oxford has gratefully accepted the Fund subscribed in memory of the late Regius Professor of Medicine, and has made the following regulations for its administration.

1. The Fund shall be called "The Osler Memorial Fund."

2. A Bronze Medal shall be awarded once in every five years to the Oxford medical graduate who shall, in the opinion of the Board of Awarders hereinafter constituted, have made the most valuable contribution to the science, art, or literature of medicine, and who has not previously received the medal.

3. For the purpose of the preceding clause the term "Oxford Medical Graduate" shall mean a person, whether man or woman, who has taken the degrees of Bachelor of Arts and Bachelor of Medicine at the University of Oxford.

4. The Board of Awarders shall be constituted as follows: The Vice-Chancellor; two professors of the Faculty of Medicine elected by the Board of the Faculty of Medicine; two persons not being members of the University elected by the Hebdomadal Council on the recommendation of the Board of the Faculty of Medicine. The elected members of the Board of Awarders shall hold office for five years and be re-eligible.

5. All expenses in connexion with the award of the Bronze Medal shall be paid out of the income of the Fund.

6. The residue of the income of the Fund may be used at the discretion of the members of the Board of Awarders resident in Oxford in making grants from time to time to teachers in the Oxford Medical School, recognised as such by the Board of the Faculty of Medicine, to enable them to pursue some special study connected with medicine outside the University.

7. Applications for such grants shall be made to the Dean of the School of Medicine, who shall act as secretary to the Board of Awarders.

Osler Memorial Medal.

The first quinquennial award of the medal was made on June 12th to Sir Archibald E. Garrod. The Board of Awarders consisted of the Vice-Chancellor (the Warden of Wadham), Sir Charles Sherrington, Sir Humphry D. Rolleston, and Sir William B. Leishman.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow; New Lectureships in Pathological Biochemistry.

THE University, the Royal and the Western Infirmaries of Glasgow have recently received considerable benefactions for the purpose of promoting the advancement of medical knowledge by biochemical and other scientific methods. At each infirmary suitable laboratories are being provided and equipped, and the University has agreed to coöperate by providing at each a university lecturer in pathological chemistry, who shall also be appointed, by the infirmary, its clinical biochemist. The stipend of the joint post, which is a whole-time one, will be £700 a year. The duties include the practical instruction of students and practitioners in biochemical methods, the advancement of medical knowledge by scientific investigation, and the assistance of the clinical staff by making chemical examinations and tests in relation to their patients. It is expected that the first appointments to the new posts will be made during the summer.

A Nursing Home for Civil Servants.

The Civil Service Scottish Advisory Committee is forming the East of Scotland Civil Service Nursing Association, Limited, to provide medical and surgical institutional treatment for Government servants and their dependants. A fully-equipped nursing home, with accommodation for 12 patients, has been acquired in the centre of Edinburgh. Men will pay an annual subscription of 12*s.* and women of 8*s.*, with a small entrance fee. Patients will pay an inclusive rate of £3 3*s.* per week.

The British Medical Association in Scotland.

The Scottish office of the British Medical Association is only five years old, but so rapidly has the Association grown north of the Tweed that a new central office has been found necessary, and on June 4th the Scottish House, at 6, Drumsheugh-gardens, Edinburgh, was opened by Sir John Gilmour, Secretary for Scotland. The proceedings took the form of a luncheon at which Dr. C. E. Douglas, Chairman of the Scottish Committee, presided. Sir John Gilmour, who proposed the toast of the British Medical Association, after referring to the widespread activities of the Association in the United Kingdom, said that they must also be made Empire-wide. As the years progressed it was found that medical problems at home were influenced by repercussions from other parts of the King's dominions. Naturally there were certain differences between the work of those across the Border and their Scottish confrères, and mutual efforts for understanding, wisely used, would be of great benefit to all. It was a high pleasure, he said, as President of the Board of Health in Scotland, to be associated with such efforts, and he believed the relationship between the Association and other medical bodies and the Board of Health in Scotland had been not only of a friendly but essentially of a useful nature. In his reply, Dr. R. A. Bolam, Chairman of the Council of the British Medical Association, expressed his pleasure that the Imperial bearing of the Association was recognised in high quarters, and Dr. Douglas, in assuming custody of the House, remarked that although in some respects it was necessary for the medical profession to behave through the Association as a trades-union—that was to say, they had to defend the interests of the profession—there had not been a single action of the Association that had been contrary to the public interests. Other toasts included The City of Edinburgh, proposed by Dr. R. C. Buist, Dundee, and replied to by Lord Provost Sir William Sleigh; Floreat res Medica, by Sir Robert Philip; and The Chairman, by Dr. H. B. Brackenbury. Among those present were many representatives of medical and associated bodies, including Lord MacKenzie, Mr. N. Bishop Harman, Dr. A. Cox, Mr. L. Ferris-Scott, Dr. James R. Drever, Prof. G. Lovell Gulland, Prof. T. K. Monro, Prof. Lorrain Smith, Prof. Currie, Sir David Wallace, Prof. B. P. Watson, Sir Robert Philip, Prof. G. M. Robertson, Dr. A. K. Chalmers, the President of the Royal Medical Society, Edinburgh, Mr. W. J. Dobie (solicitor to the Association in Scotland), and Mr. Rutherford Hill (secretary, Pharmaceutical Standing Committee).

Crippled Scottish Children.

A fund is being raised in Edinburgh to provide the preliminary expenses of a clinic at which massage and remedial gymnastics will be available at a low cost for the poorer class of patient. At present there is in Scotland no adequate organisation for dealing with crippled children.

The recent "Day of Remembrance" for Edinburgh Royal Infirmary produced over £6000. The collecting boxes contained 240 bright new farthings and a number of Russian roubles.

Obituary.

SAMUEL TAYLOR DARLING.

Dr. S. T. Darling, of the United States of America, member of the League of Nations Malaria Committee, whose sad death as the result of a motor accident near Beirut, Syria, we announced recently,[1] was a pathologist of unusual distinction.

He was born in Harrison, New Jersey, in 1872. He received his degree in medicine at the College of Physicians and Surgeons, Baltimore, in 1903. From 1906 to 1915 he held the post of chief of laboratories of the Isthmian Canal Commission, Panama Canal Zone. His research studies in tropical medicine during this period won him wide recognition among the medical profession. In 1913–14 he accompanied General Gorgas on a sanitary mission to the Rand Mines and Rhodesia, South Africa. In 1915 he joined the staff of the International Health Board, and for the next three years he headed a medical commission engaged in investigating the causes of anæmia among the people of Malaya, Java, and Fiji. From 1918 to 1920 he served as professor of hygiene and director of laboratories of hygiene in the Medical School of Sao Paulo, Brazil. Since that time he had been director of a field laboratory for research studies in malaria located at Leesburg, Georgia. He was recently appointed corresponding member of the Malaria Commission of the League of Nations. At the time of his death he was travelling with the Commission which was investigating the prevalence of malaria in Palestine and Syria.

---

[1] THE LANCET, May 30th, p. 1159.

Dr. Darling was an honorary Fellow of the Royal Society of Tropical Medicine and Hygiene, London, he and General Gorgas being the only Americans so honoured. He had accepted an invitation to deliver the annual address to the society next month. He was also a Fellow of the American Medical Association and a corresponding member of the following organisations: Helminthological Society, Washington, D.C., the Malaria Commission of the Health Section of the League of Nations, Société de Pathologie Exotique de France, and Sociedade de Medicine e Cirurgia de Sao Paulo, Brazil. He was president of the American Society of Tropical Medicine for the year 1924–25. His published works include important contributions to our scientific knowledge of malaria, relapsing fever, dysentery, and parasitic diseases, particularly hookworm disease, filariasis, and trypanosomiasis.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	473	13	6
Dr. A. F. Hurst	5	5	0
Dr. F. A. Coward	1	1	0
Dr. A. Rose	1	1	0
Dr. J. W. Carr	1	0	0
Anon.	0	10	6
Dr. J. A. Beals	0	5	0
	£482	16	0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

RUTHERFORD MORISON TESTIMONIAL.

THE following is the third and final list of subscriptions to this Fund, the grand total of which, including subscriptions promised, amounts to £1528:—

Third Subscription List.

£52 10s.—Prof. C. Saint (Newlands, C.P.).

£15 15s.—Dr. Mary S. Gordon (Johannesburg).

£10 10s.—Prof. R. P. Ranken Lyle (Newcastle), Dr. W. Frank Wilson (Newcastle), Mr. F. C. Pybus (Newcastle), Mr. T. A. Hindmarsh (Newcastle), Mr. J. Collingwood Stewart (Newcastle).

£5 5s.—Dr. J. S. Arkle (Newcastle), Dr. O. W. Ogden (Newcastle), Dr. G. A. Atkinson (Newcastle), Dr. P. R. Ingram (Muswell Hill), Mr. A. Hedley Whyte (Newcastle), Dr. D. A. Dewar (Stanley), Mr. C. W. MacGillivray (Edinburgh), Dr. E. Craig Dunlop (Carlisle), Mr. J. W. Leech (Newcastle), Mr. F. J. Nattrass (Newcastle), Prof. R. Howden (Newcastle), Dr. McAleenan (Blaydon), Dr. A. Parkin (Newcastle), Dr. R. Dagger (Newcastle), Dr. Mary E. Howie (Newcastle), Dr. George Hall (Newcastle), Dr. C. G. Irwin (Tynemouth), Dr. R. W. Nevin (Newcastle), Dr. D. Wells Patterson (Newcastle), Mr. J. D. Wardale (Newcastle).

£5.—Mr. Harvey Evers (Newcastle), Dr. R. Wilkie Smith (Whickham).

£4 4s.—Dr. A. R. S. Jack (West Hartlepool), Dr. F. F. T. Hare (Durham).

£3 3s.—Dr. Ritson (Hexham), Dr. W. J. Phillips (Forest Hall), Mr. J. Brumwell (Newcastle), Mr. W. E. M. Wardill (Newcastle), Dr. J. M. Gover (Gosforth), Dr. Norris (Gateshead), Dr. J. C. Grant (West Boldon), Dr. G. E. Stephenson (Newcastle), Dr. E. E. Chapman (Hartlepool), Dr. I. G. Modlin (Sunderland).

£2 2s.—Dr. Hedda Alstron (Chipperfield), Dr. A. C. Jap (Singapore), Dr. W. Herbertson (Newcastle), Dr. J. Donaldson (Selukwe, S. Rhodesia), Dr. H. D. MacPhail (Newcastle), Dr. H. C. Coxon (Leamington), Dr. W. Kerr Russell (Newcastle), Mr. H. Frankling (Harrogate), Dr. G. E. Lloyd (Hexham), Dr. T. N. V. Potts (Newcastle), Dr. C. C. Robertson (Darlington), Dr. C. G. R. Goodwin (Barrasford), Dr. P. Holgate (North Shields), Captain J. A. Charles (Stanley), Dr. A. Dryden (Newcastle), Dr. J. W. Gibson (Newcastle), Dr. W. Pattullo (Spennymoor), Dr. W. Hudson (Bedlington), Dr. Langenberg (Houghton-le-Spring), Dr. A. Livingston (Newcastle).

£1 1s.—Dr. H. Widdas (Shildon), Dr. P. Vernon Anderson (Shildon), Dr. Janet A. Vaughan (Kachmir), Dr. O'Callaghan (South Shields), Dr. Hamilton (South Shields), Dr. P. A. Mackay (Newcastle), Dr. E. T. Colville (Newbiggin), Dr. L. F. Browne (London), Dr. R. B. Lishman (Felling), Dr. Whitley (Newcastle), Dr. M. Maclean (Ashington), Dr. H. S. Brown (Choppington), Dr. T. D. Silverston (Preston), Surgeon Commander G. O. M. Dickenson (London), Dr. L. H. Hunter (Middlesbrough), Dr. J. B. Alderson (Ryhope), Dr. H. V. Ingram (South Shields), Dr. William C. Haswell (Strensall), Dr. A. P. Lloyd (Penshaw), Dr. Herbert Christal (Hoxne), Dr. Mary Douglas (Newcastle), Dr. R. Ford Tredre (St. Blazey), Dr. Bendle (London), Dr. G. Howell (Newcastle), Dr. James Smith (Newcastle), Dr. A. B. MacPherson (Sunderland), Dr. Helen C. Buckell (Shipley), Dr. Milbanke (Sunderland), Dr. D. McArthur (Bury St. Edmunds), Dr. T. R. Pearson (Torquay), Dr. Miller (Bellingham), Dr. Ian Macdonald (Huelva, Spain), Dr. R. A. Welsh (Felton), Dr. F. H. Kennedy (Pershore), Dr. G. A. Mason (Sunderland), Dr. Catherine M. Jones (Swansea), Dr. N. A. Eddlestone (Whitley Bay), Dr. H. R. Smith (Newcastle), Dr. H. R. Smith (Newcastle) (second donation), Dr. Dickson (Hexham), Dr. C. J. Neilan (Seaham), Dr. W. T. Hall (Heaton), Dr. K. B. Allen (Bathurst, West Africa), Dr. W. Smith (Gateshead), Dr. A. T. Harrison, jun. (Sherburn), Dr. H. C. Rollin (Durham), Dr. T. L. Crawhall (Durham), Dr. S. K. Young (Chester-le-Street), Dr. Carina A. B. Lewis (Thames, N.Z.).

£1.—Dr. S. A. Shehid (Minia, Egypt), Dr. H. McAllum (Inglewood, N.Z.), Dr. W. C. Wardle (Middlesbrough).

10s. 6d.—Dr. W. H. Davis (Low Fell), Dr. Revie (Ashington).

10s.—Dr. Williams (Haltwhistle), Dr. E. F. Dawson Walker (Durham).

Subscriptions Promised, but Amounts Not Specified.—Dr. Sally Allen (Newcastle), Dr. S. K. Norris (New Brancepeth), Drs. J. and G. Denholm (Meadowfield).

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. E. S. Wilkinson and Surg. Comdr. W. Bastian are placed on Ret. List with the rank of Surg. Capt.

E. O'Reilly and J. Cussen to be Surg. Lts.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. H. O. Martin to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

REGULAR ARMY RESERVE OF OFFICERS

Lt.-Col. E. P. Hewitt having attained the age limit of liability to recall ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. A. P. Watson to be Lt.-Col., and to command the 11th (2nd Scottish) General Hospital, vice Lt.-Col. (Bt.-Col.) D. J. Graham, vacated on completion of tenure.

D. L. Greig to be Lt.

To be temp. Lts. whilst employed as Dental Surgs.: Lts. A. P. McClare (and relinquishes the rank of Lt.) and A. Hughes.

ROYAL AIR FORCE.

P. D. Barling is granted a short service commission for three years on the active list as a Flying Officer.

INDIA AND THE INDIAN MEDICAL SERVICE.

Bhagwant Kishore Sikand, Des Raj Kajuria, and Arukkattur Rangaswamy Srinivasan to be Temp. Lts.

Capt. S. N. Hayes has handed over charge of the duties of superintendent of the District Jail at Dera Ghazi Khan. Maj. J. F. James, civil surgeon, Naga Hills, officiates as Civil Surgeon, Darrang, vice Lt.-Col. W. D. Richie, placed on special duty; Capt. C. H. P. Allan has been posted as Supernumerary Civil Surgeon, Cachar; Lt. E. F. Hottinger, civil surgeon, has been transferred to Mianwali; Lt.-Col. G. Hutcheson, officiating Inspector-General of Civil Hospitals, United Provinces, has been nominated to be President of the Indian Provinces Medical Council, vice Col. A. W. R. Cochrane, resigned; Maj. A. S. Leslie, on relief from appointment of district medical officer, South Canara, has been posted to the Government General Hospital, Madras; Maj. R. G. G. Croly acts as First Surgeon, General Hospital, and Professor of Surgery, Medical College, Madras, vice Lt.-Col. E. W. C. Bradfield.

Correspondence.

"Audi alteram partem."

PERIODICITY OF CHOLERA.

To the Editor of The Lancet.

Sir,—In his interesting note in your issue of June 13th Major A. J. H. Russell states that he has discovered a regular "six-year cycle" of epidemic cholera prevalence in Madras and other parts of India, and as far as he can discover "no such periodic trend has been previously demonstrated in connexion with this disease." He may therefore be interested in looking up in the index of my work on "Bowel Diseases in the Tropics" the heading Cycles of Cholera Years, where he will find a brief discussion on a "Three-year Cholera Cycle" described by H. W. Bellew in his work of 1885 on the "History of Cholera in India," as well as a reference to the interesting study of the Epidemiology of Cholera in Southern India, by A. Herbert in the *Indian Medical Gazette* of 1894. It is, of course, well known that various communicable diseases tend to become epidemic at intervals of several years, including cholera and small-pox—the latter having been described by J. A. Laing in the Madras Sanitary Report of 1891 to recur at intervals of seven years in that province—although, if a sufficiently long series of years is examined, they are not very regular as far as my own studies of cholera in India are concerned.

It so happens that I have spent much time recently in a study of the epidemiology of cholera in India over a larger series of years than Major Russell refers to in his note, and have come to the conclusion, which I hope to be able to formulate before long, that the major cholera epidemics which originate in Bengal and spread at irregular intervals over large parts of India causing hundreds of thousands of deaths in a single year, *can* be foreseen in time to allow sanitary measures to be taken to control to some extent the dissemination of the disease by pilgrimages and fairs; although I find the conditions giving rise to cholera epidemics are not quite so simple as any "three-year" or "six-year" cycles, whichever period may ultimately prove to approximate the more nearly to the facts.

I am, Sir, yours faithfully,

London, June 14th, 1925. Leonard Rogers.

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

To the Editor of The Lancet.

Sir,—I agree with Mr. G. C. Cathcart that in the electrophonoide method of Zund-Burguet we have a useful means of alleviating certain cases of deafness which have failed under other methods. I have been using an electrophonoide for two years, and though my results have not been quite so satisfactory as Mr. Cathcart's, I have found it well worth the time and patience required in its use.

I have found no response in cases of syphilis, the various arsenical preparations used in treatment seem to have a destructive effect on the nerves, and this holds good also in cases of malaria where quinine has been given. The method has been disappointing in cases with tinnitus of long standing, but in two cases with Ménière's symptoms the results were gratifying. These patients were both women who had become chronic invalids, the vertigo, tinnitus, and sickness being so severe for weeks together as to keep the patients continually in bed, and these symptoms continued even when the patients were in a recumbent position. One patient has had no attacks for a year, and the other has greatly improved in every way, and has not had an attack for four months. Both are now able to take ordinary exercise.

I am, Sir, yours faithfully,

Anthony McCall, M.D.

Bournemouth, June 15th, 1925.

THE BABINSKI RESPONSE IN ECLAMPSIA.

To the Editor of The Lancet.

Sir,—In the article by Prof. T. R. Elliott and Dr. F. M. R. Walshe in The Lancet of Jan. 10th (p. 65) it was stated that eclampsia did not lead to an extensor response. In the first instance in which the Babinski symptom was observed the illness was complicated with lethargic encephalitis. In another case the association with status epilepticus seemed to be responsible for the appearance of the extensor type. In the obstetrical text-books its behaviour is not mentioned. According to the authors, it may be expected in eclampsia, because the latter is a toxic state often associated with serious destruction of the liver.

In this connexion some observations which I published in the *Neurologisches Centralblatt* (1913, No. 17) may be of interest. In a case of eclampsia with extensor response histological examination revealed the presence in several capillaries of large square cells, which remained hanging like emboli. The nuclei of these cells showed partly pyknosis, partly karyorrhexis. Some were in a state of mitosis, so that several equatorial plates were visible. Slight lymphocytosis was present, and in the liver some cellular dissociation. In this case, then, emboli in the cerebral capillaries were formed by fœtal cells identical with the syncytium cells which wander into the maternal venous cavities. These emboli are, it is true, not essentially specific for eclampsia, because they sometimes occur in normal pregnancy, but when they are present in great numbers in eclampsia with extensor response, we can hardly help supposing that they may play a rôle in the manifestation of Babinski symptom, perhaps in association with the toxic state.—I am, Sir, yours faithfully,

Ladislaus Benedek,
Director of the Neurological Clinic,
June 12th, 1925. Debrecen, Hungary.

Medical News.

Royal College of Surgeons of England.—At a recent meeting of the Council of the College the President, Sir John Bland-Sutton, in the chair, Mr. Graham Simpson, surgeon to the Royal Hospital, Sheffield, and lecturer in surgery at the University of Sheffield, was elected a member of the Court of Examiners in Surgery. Mr. Cecil Pembrey Grey Wakeley was elected a member of the Board of Examiners in Anatomy for the Fellowship for the ensuing year. Mr. John Basil Hume was elected a member of the Board of Examiners in Anatomy under the Conjoint Board. Dr. William Porter MacArthur was appointed an examiner in Bacteriology and Dr. P. H. Manson-Bahr was appointed an examiner in Diseases and Hygiene of the Tropics for the Diploma in Tropical Medicine and Hygiene. Mr. C. B. Goulden was elected a member of the Board of Examiners in Ophthalmic Medicine and Surgery. Dr. F. L. Golla was appointed an examiner in Psychological Medicine. Mr. E. B. Dowsett and Mr. A. T. Pitts were appointed additional members of the Board of Examiners in Dental Surgery.

The following gentlemen were elected professors and lecturers for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith: On the Evolution of the Higher Primates. Arthur Edmunds: On Pseudo-Hermaphrodism and Hypospadias and their Surgical Treatment. Joseph Ebenezer Adams: On the Surgery of the Jejunum. Edward Musgrave Woodman: On Malignant Disease of the Œsophagus. Arthur Tudor Edwards: On the Surgical Treatment of Phthisis and Bronchiectasis. Arthur Lawrence Abel: On the Treatment of Cancer of the Œsophagus. Hugh William Bell Cairns: On Neoplasms of the Testicle.

Arris and Gale Lecturers.—Stanford Cade: On Cholecystography. Alfred Piney: On the Importance of Hæmatology in Surgery.

Erasmus Wilson Lectureship.—Clement E. Shattock: Demonstrations on Pathology.

Arnott Demonstratorship.—Sir Arthur Keith: Demonstrations on the Contents of the Museum.

Diplomas of Fellow were conferred upon 24 candidates as the result of the recent examination, for which 101 candidates presented themselves. Of these candidates, 27 were successful and 74 were rejected. Three candidates have not yet complied with the by-laws and are therefore no entitled to receive the diploma. The following are the names and medical schools of the successful candidates :—

Noel F. Adeney, Cambridge and St. Mary's ; George Armitage, Leeds ; Geoffrey M. F. Barnett, Otago and Middlesex ; Arthur C. B. Biggs, Univ. Coll. ; Cyril M. Brophy, Univ. Coll. and St. Bart.'s ; John D. M. Cardell, St. Thomas's ; Guy O. Chambers, St. Bart.'s ; Harry K. Christie, Otago and Guy's ; Cecil C. Coghlan, Sydney, Dublin, and Guy's ; William M. Cotter, Otago and St. Bart.'s ; Milton Geaney, Sydney and Guy's ; Frank Hudson, Univ. Coll. ; John A. James, Sydney and Guy's ; Basil L. Laver, Guy's ; Vaman R. Mirajkar, Bombay and St. Bart.'s ; John R. Nicholson-Lailey, Bristol and London ; James B. Oldham, Liverpool ; Cyril M. Pearce, St. Bart.'s ; Kenneth N. Purkis, Guy's ; Mohammed M. Riad, Cairo and St. Bart.'s ; Andrew Rugg-Gunn, Edinburgh and St. Mary's ; Ronald C. Shaw, Manchester ; Maurice P. Susman, Sydney, Middlesex, and St. Bart.'s ; and Charles A. Wells, Liverpool.

The diploma of Fellow was also conferred upon Max A. Lautré, St. Thomas's, who has previously passed the examination and has now attained the age of 25 years.

Diplomas of Member were conferred upon Eileen S. Morris, Univ. Coll., and Marie Pedersen, Royal Free, who have now complied with the necessary by-laws.

INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.—At the conclusion of the London programme on June 6th the members of this Assembly proceeded on a three days' visit to the Midlands from Monday, June 8th, to Wednesday, the 10th. It is stated that owing to the number of visitors who wished to inspect Leeds, over 600 out of the 700 delegates, a ballot was held in London previously, whereby the party was divided into three, each section visiting respectively Liverpool, Manchester, and Leeds.

Liverpool.—All the hospitals of the city were united in providing an extensive and varied programme. The general principle was that the mornings should be devoted to visits to the hospitals, operations, demonstrations, and clinical lectures being provided daily from 9 A.M. till 12.30. The Liverpool Medical Institution was used as a central bureau, where tickets and information were distributed each morning at 8.30. Much appreciation was expressed of the adequacy of the arrangements and of the excellence of the clinical material provided. In a special degree the surgery of Liverpool aroused the approval of the visitors. On Monday afternoon a united meeting was held at the Medical Institution. From 2 to 4 there was a series of short papers on subjects of varied interest. Prof. Ernest Glynn spoke on Tumours of the Suprarenal Cortex and their relation to Virilism, Prof. John Hay on High Blood Pressure, Dr. Dingwall Fordyce on the Hygiene of the Cripple Child, and Dr. R. J. Minnitt on Insulin in the Treatment of Post-anæsthetic Complications. The papers elicited well-informed criticism. After a brief interval for tea a series of instructive cases was shown, illustrating the surgery of children, orthopædic work, skin diseases, and other conditions of special interest. Dr. R. W. Mackenna demonstrated an excellent series of wax casts, gathered together in the course of his dermatological practice. Tuesday and Wednesday afternoons were given up to visits to outlying institutions, such as the Royal Liverpool Children's Hospital (Country Branch) at Heswall, the Liverpool Children's Open Air Hospital at Leasowe, and the City Sanatorium and Isolation Hospital at Fazakerley. At Heswall Sir Robert Jones and his colleagues on the staff drew an appreciative audience to their beautifully situated hospital overlooking the Dee, while at Leasowe Dr. T. H. Martin demonstrated the good results obtained in the treatment of surgical tuberculosis in children under the ægis of the Liverpool Child Welfare Association. At Fazakerley the visitors were welcomed by Sir John Ulling, M.D., and conducted round by Dr. C. Rundle, the medical superintendent, and Mr. John T. Morrison, the consulting surgeon. Perhaps the greatest interest was aroused in the arc light department, and the results of treatment in the cases seen there. An account of the visit would be very incomplete which contained no allusion to the civic reception given by the Lord Mayor on Tuesday evening at the Town Hall. A distinguished gathering was addressed by the Lord Mayor and by Dr. Charles Mayo. The note of welcome was warmly responded to and feelings of appreciation generously expressed, not only of the scientific and medical work seen, but also of the Englishman's fine qualities of character and personality, above all his sense of the value of the things best worth having. On Monday the "staffs of the Liverpool hospitals" were "At Home" in the Walker Art Gallery, where many Americans found friends, whilst all enjoyed the fine collection of pictures.

Manchester.—The party visiting Manchester necessarily split itself up into sections, attending lectures and demonstrations in the matters most interesting to each. On the three mornings visits were arranged to local hospitals, including the Royal Infirmary, Salford Royal Hospital, Ancoats Hospital, and Crossley Sanatorium. At the Royal Infirmary medical and surgical cases were shown, and among others the X ray, aural, and electrocardiographic departments were inspected. On Monday afternoon a formal welcome was given by the Vice-Chancellor of the University, and between 2.30 and 5 a series of lectures was held at the University. These included the Diagnosis of Jacksonian Epilepsy by Mr. G. Jefferson ; Success and Failure in Organotherapy by Prof. G. R. Murray ; Formation of Bone in Soft Parts by Prof. J. S. B. Stopford ; and Infective Labyrinthitis : its Rôle in the Production of Otitic Meningitis and its Surgical Treatment, by Sir William Milligan. The various departments of the University were inspected and in the medical library an exhibition of rare medical books was on view. The non-medical members of the party inspected the docks and part of the Manchester Ship Canal on a tug placed at their disposal by the directors. On Tuesday a visit was paid to Rylands' Library, and a lunch was given at the Midland Hotel at the invitation of the Manchester Branch of the Anglo-American Society. In the afternoon the following series of lectures was given at the Royal Infirmary : Arterial Insufficiency, by Dr. J. C. Bramwell ; the Experimental Study of Epidemics, by Prof. W. W. C. Topley ; Gynæcology in Manchester, by Dr. A. Donald ; Symptomless Hæmaturia, by Mr. A. H. Burgess ; the Surgical Treatment of Arthritis Deformans, by Mr. H. Platt. A party was taken to view the Royal Exchange, by invitation of the chairman of the board of directors, and in the evening a civic reception was given to the delegates by the Lord Mayor and Corporation in the Town Hall. On Wednesday a party visited Richard Haworth and Company's cotton mill, and a lunch was given at the Midland Hotel on the invitation of the medical staffs of the Manchester hospitals.

Leeds.—A full programme was arranged in advance for the visitors, starting each day at the Medical School at 9 A.M., and at the various departments lectures and demonstrations were held until 6 P.M. The departments of anatomy, pathology, and surgery occupied the mornings ; medicine, including neurology and children's diseases, the afternoons until 5 o'clock. The work of the eye and ear cliniques, X ray diagnosis, and X ray therapy were demonstrated between 5 and 6. On Monday the party was welcomed by Dr. J. K. Jamieson, Dean of the Faculty of Medicine of Liverpool University. Among the lectures and demonstrations Dr. J. Burrow spoke on Some Problems of Cardiac Disease, and Prof. W. H. M. Telling gave Some Remarks on Sigmoid Diverticulitis. Sir Berkeley Moynihan delivered an address on the subject of gall-stones. It was unfortunate that owing to the arrangements made by the organisation of the visitors themselves, they were late in arrival for the demonstrations every day except Wednesday, when those of the party stationed in the city attended the cliniques. On the other days a journey from Lancashire had to be made. The necessity of an early departure by train, and a late arrival in the mornings took the edge off the programme, and many of the demonstrations were badly attended. However, the experience gained and the hasty friendships made will enable the next meeting to be a greater success. The surgical cliniques in the middle of the morning attracted most attention. On Wednesday morning the Lord Mayor welcomed the members of the Association, and Dr. C. Mayo made a happy speech in reply.

On Wednesday evening the whole of the delegates sailed from Liverpool by special steamers for Ireland.

Dublin.—The Association visited Dublin in two parties, from Thursday, June 11th, to Monday, June 15th, inclusive. The first party spent the Thursday and Friday in Dublin and then changed places with a similar party which had gone first to Belfast. For the four days of their stay in Dublin the visitors were invited to spend what time they chose each morning in the several hospitals, where interesting cases were shown by surgeons and physicians, and where special series of operations were performed. This was probably the part of the programme which the visitors enjoyed most. In addition three special sessions for exhibition of cases were held in the Physics Theatre of University College, the authorities of which institution took special pains to provide for the comfort of their visitors. On Thursday morning, on their arrival, the Americans were welcomed at the Royal College of Physicians by the President, Sir William Thompson. In the afternoon a discussion was held at University College on exophthalmic goitre, Prof. F. O'Carroll presiding. The discussion was opened by Prof. T. G. Moorhead, who was followed by Dr. Charles Mayo and Drs. T. G. Hardman and H. F. Moore. On Friday morning, under the presidency of Sir James Craig, a discussion took place on encephalitis lethargica. The discussion was opened by Prof. F. C. Purser, and a series of some 20 cases exhibiting various sequelæ was shown. On Saturday morning, after the exhibition of some medical cases, a discussion on puerperal sepsis was opened by Dr. G. FitzGibbon, Master of the Rotunda Hospital, who was followed by Prof. J. W. Bigger and Prof. R. J. Rowlette. A pleasant interchange of honours took place between the American and Irish professions. At one of the early meetings

Dr. Charles Mayo announced the election of a number of honorary members of the Inter-State Post-Graduate Assembly. They were: Dr. D. J. Coffey, President of University College; Sir William Thompson, President of the Royal College of Physicians of Ireland; Mr. R. C. B. Maunsell, President of the Royal College of Surgeons in Ireland; Sir James Craig, President of the Royal Academy of Medicine in Ireland; Prof. J. F. O'Carroll, Sir Robert Woods, Sir William Taylor, Prof. F. C. Purser, Prof. T. G. Moorhead, Mr. A .Blayney, Dr. T. P. C. Kirkpatrick, Mr. A. A. McConnell. At a later stage the election of Mr. T. Healy, Governor-General, was announced.

On Friday afternoon, at the Royal College of Physicians, the Honorary Fellowship of the Royal Academy of Medicine was conferred on Dr. Charles Mayo, and in absentiâ on Dr. George Crile. The University of Dublin has passed graces for conferring honorary degrees on Dr. Mayo and Dr. Crile, and the ceremony will take place later in the month. The arrangements for social entertainments were thorough and comprehensive. On Thursday evening President Cosgrave and the Executive Council held a reception in the National Museum, at which a large number of guests had the opportunity of studying the unique collection of Irish antiquities, as well as many other objects of interest. On Saturday afternoon, in the beautiful grounds of the Viceregal Lodge, His Excellency the Governor-General gave an equally pleasant reception. Many of the American visitors took advantage on Sunday of their honorary membership of the several Dublin golf clubs, and enjoyed a game in beautiful surroundings. The visit ended on Monday with the departure of the last of the guests for Scotland.

Belfast.—A similarly varied and hospitable programme was provided here. The various hospitals and institutions of the city were visited, and addresses given, resulting in debates upon salient medical and surgical subjects. At Mount Stewart Lord and Lady Londonderry gave an afternoon garden reception, and at Queen's University Lord Londonderry, the Chancellor, conferred an Honorary LL.D. on Dr. Charles Mayo, Dr. H. Cabot, and Dr. Franklin Martin.

LONDON TEMPERANCE HOSPITAL.—Princess Arthur of Connaught last week opened additions which include the Vezey Strong Memorial Home, which will accommodate 33 sisters and nurses. An improved operating theatre, an X ray room, an anæsthetising room, a recovery room, a surgeons' room, and a sterilising room are among the additions. Students will watch operations from behind a glass screen. Every bedroom in the nurses' home is fitted with hot and cold water.

UNIVERSITY OF LEEDS.—Dr. W. H. Maxwell Telling, who has occupied the Chair of Therapeutics in the University of Leeds for the past two years, has been elected by the Council of the University Professor of Medicine and head of the Department of Medicine, as from Oct. 1st next, on the retirement from that office of Dr. T. Wardrop Griffith. —Dr. R. A. Veale has been elected to the Chair of Therapeutics in place of Prof. Maxwell Telling, and Dr. G. W. Watson has been elected to the Chair of Clinical Medicine, which has been vacant since the retirement of Dr. A. G. Barrs.

TABLET TO THE MEMORY OF DR. T. D. LISTER.—At the National Sanatorium, Benenden, Kent, on the occasion of a lunch given by the Council of the National Association for the Prevention of Tuberculosis to the delegates to the conference of the Post Office Sanatorium Society on May 30th, a memorial tablet was unveiled to Thomas David Lister, C.B.E., M.D., M.R.C.P. Dr. Lister, who was born in 1869 and died in 1924, had given devoted service to the anti-tuberculosis campaign and was one of the founders of the Benenden Sanatorium, the plans for which had been his special study. The tablet, which is placed in the entrance hall, was erected by the Council of the National Sanatorium Association.

TOUR TO THE HEALTH RESORTS OF FRANCE.—The nineteenth Voyage d'Etudes Médicales to the health resorts of France (which has been previously announced in these columns) will take place from Sept. 2nd-15th. The party will meet at Vittel at 5.30 P.M. on Sept. 2nd, and during the subsequent 13 days will visit the following places: Contrexéville, Martigny-les-Bains, Bourbonne-les-Bains, Bains-les-Bains, Plombières-les-Bains, Luxeuil-les-Bains, Bussang, Gerardmer, La Schlucht, Munster, Colmar, Soulzbach and Soulzmatt, le Linge, les Trois Epis, Aubure, Ribeauville, Chatenois, Barr, Sainte-Odile, Le Hohwald, Schirmeck, Strasbourg, Niederbronn, Morsbronn, Luxembourg, Mondorf, Thionville, Sierck-les-Bains, Spa, Nancy-Thermal, Sermaize-les-Bains. The cost of the voyage has been fixed at 1150 francs which includes all expenses throughout the voyage. English doctors desirous of participating in this trip are asked to communicate without delay with Madame M. C. Juppé-Blaise, representative of the French Spas, at the Office Français du Tourisme, 56, Haymarket, London, S.W. 1.

UNIVERSITY OF LONDON: LONDON HOSPITAL MEDICAL COLLEGE.—The Liddle Triennial prize of £120 for 1925–26, which is open to public competition, will be awarded for the best essay on the Ætiology and Treatment of Primary High Blood Pressure. The essays must be submitted not later than Jan. 30th, 1926, addressed to the Dean of the College, from whom further particulars may be obtained.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART. On June 13th the foundation-stone of the extension to the out-patient department of the hospital in Westmoreland-street, London, W. 1, was laid by the Grand Master of the Order of Crusaders, Colonel W. Faber. About 300 Crusaders in their striking costumes attended service at St. Marylebone Parish Church and afterwards proceeded to the ceremony, led by the sword-bearer. After the stone had been laid, the Chairman, Mr. E. R. Morris, at a meeting in the main hall, outlined the growth and work of the hospital since its inception 68 years ago. About £7000, he stated, was required to cover the cost of the extensions.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The thirty-first meeting of the Commission was held at the Home Office, Whitehall, on June 11th, Lord Lawrence of Kingsgate in the chair. Evidence as to the nature, extent, cost, and administrative arrangements of optical and ophthalmic treatment of insured persons was given by the Joint Council of Qualified Opticians, represented by Mr. J. H. Sutcliffe, Mr. F. W. Bateman, and Dr. Margaret Dobson; by the British Optical Association, represented by Mr. W. B. Barker, Mr. McHoul, and Mr. Meynell; by the Council of British Ophthalmologists, represented by Mr. E. Treacher Collins, Mr. J. Herbert Fisher, and Mr. M. S. Mayou; and by the Ophthalmic Benefit Committee, represented by Mr. H. L. Eason, Mr. C. F. Harford, and Mr. G. H. Pooley. Proof copies of the oral evidence and the relative statement submitted at the meeting of May 21st are now on sale at H.M. Stationery Office (2*s.* 3*d.*).

POWERS OF MEDICAL REFEREES.—An important reserved judgment in regard to the rights of a medical referee under the Workmen's Compensation Act was delivered by Judge Ruegg, K.C., at Stoke-on-Trent on June 3rd. A colliery engine-man claimed compensation from the Berryhill Collieries, Limited, Stoke-on-Trent. The applicant was certified to be suffering from miner's nystagmus by the certifying surgeon, but the employers appealed to the medical referee, who found that the man was suffering from nystagmus at the time of the examination, but was not thereby disabled from earning full wages at the work at which he was employed. The question was whether he (the judge) had any power to interfere with that finding. In his judgment he had not, and he dismissed the application for compensation. The judge's own experience was that it would be very difficult for any court to find a man had a reasonable chance of obtaining employment if he had been suffering from nystagmus, and he remarked, "I have the gravest doubt in my own mind as to whether the Act of Parliament ever meant that the medical referee should have such extensive powers given to him. It is clearly meant that he should have final power with regard to the disease, but with regard to all such complicated questions as now arise, such as the state of industries existing in various districts, that it was ever meant it should devolve upon him I very much question."

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Dr. A. F. Hurst will lecture for the Fellowship of Medicine on Friday, June 26th, at 5.30 P.M., in the West Lecture Hall, 1, Wimpole-street, and the subject chosen is the Treatment of Cholecystitis and the Prevention of Gall-stones. From June 22nd to July 4th the London Temperance Hospital will hold a special course from 4.30 in the afternoon for the convenience of those in general practice. Clinical demonstrations, illustrated by cases, will be given, followed by short lectures lasting half an hour, and the fee for the course is £1 1*s.* A course in urology has been arranged by the St. Peter's Hospital from June 29th to July 25th. The Queen's Hospital for Children has organised a two weeks' course from July 6th to the 18th. Classes will be held from 10 A.M. throughout the day in the various departments of the hospital. A course dealing with the diagnosis and treatment of nervous diseases will take place at the West End Hospital (O.P. Department, 73, Welbeck-street) from July 27th to August 15th. Other special courses in August are: A vacation course at the Prince of Wales's General Hospital (N.E. London Post-Graduate College), Tottenham, from August 3rd to the 15th—instruction will be offered from 10.30 A.M. until 5.30 P.M. daily; a fortnight's intensive course at the Queen Mary's Hospital (Stratford), and a urology course continuing throughout the month at the All Saints' Genito-Urinary Hospital. Copies of the syllabuses and the programme of the Fellowship of Medicine may be obtained from the Secretary at 1, Wimpole-street, London, W. 1.

A LIVERPOOL HEART HOSPITAL.—It is proposed, at a cost of £10,000, to convert a private residence in Liverpool, not far from the University, into a hospital for the treatment of heart cases. There are said to be 1500 people crippled by valvular disease of the heart in Liverpool and its district.

NEW INFIRMARY FOR HARROGATE.—The governors of the Harrogate Infirmary have adopted the recommendation of the General Committee to build a new hospital of 100 beds, capable of extension to 150 beds, at an estimated cost of about £70,000. The building will probably be completed by the summer of 1927. The site on Knaresborough-road cover six acres and will cost £6000.

REBUILDING OF MIDDLESEX HOSPITAL.—In the exercise of their discretion as trustees of the Zunz Bequest, Mr. Henry Gardner and Mr. Sam Baer have made a grant of £20,000 to the fund for the rebuilding of the hospital. The money will be used for the reconstruction and maintenance of the Annie Zunz Ward, which was provided in 1908 by a grant of £5000 from the same bequest. Towards the £500,000 required for the rebuilding about £140,000 has now been given. The students of the hospital have each promised to subscribe a penny a day for the next five years in addition to their individual gifts.

ROYAL COLLEGE OF SURGEONS IN IRELAND: ELECTION OF PRESIDENT AND OFFICERS.—The election of President, Vice-President, and Council of the College was held on June 3rd. Mr. R. Charles Butler Maunsell was re-elected President and Mr. Andrew Fullerton was re-elected Vice-President. The following were elected members of Council: Mr. John Benjamin Story, Sir Thomas Myles, Major-Gen. R. H. S. Sawyer, Sir Arthur Chance, Sir Robert H. Woods, Mr. Richard Lane Joynt, Mr. Thomas Eagleson Gordon, Sir F. Conway Dwyer, Mr. Alexander J. Blayney, Sir William Taylor, Mr. Trevor N. Smith, Mr. G. E. Pugin Meldon, Mr. Howard Stevenson, Mr. Seton Pringle, Sir William I. de C. Wheeler, Sir C. Arthur K. Ball, Mr. R. Atkinson Stoney, Mr. Edward Sheridan, and Mr. Adams A. McConnell.

CHELSEA CLINICAL SOCIETY. — At the annual general meeting of this society held recently at St. George's Hospital the following office-bearers, having been nominated by the Council, were duly elected:—President: Dr. Seymour Price. Vice-Presidents: Sir Thomas Parkinson, Dr. Rivers Pollock, Dr. E. Young, Dr. J. D. Rolleston, and Mr. Ivor Back. Council: Dr. H. A. Philpot, Dr. W. E. Robinson, Mr. Graeme Anderson, Mr. Gaymer Jones, and Mr. D. C. Fitzwilliams. Treasurer: Dr. K. Eckenstein. Secretaries: Mr. A. R. Thompson and Mr. L. D. Bailey. Dr. Gordon Lane, the retiring president, then opened a discussion on Facultative Diagnosis—the use of our powers of clinical diagnosis without resort to laboratory assistance—in which Dr. C. O. Hawthorne, Mr. Fitzwilliams, Mr. Ivor Back, Dr. Crewdson Thomas, and Mr. Thompson took part.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of the Society was held at the Connaught Rooms, Great Queen-street, W.C., on June 11th, the President, Sir John Broadbent, in the chair. After the loyal toasts, the Harveian Society was proposed by Sir Humphry Rolleston, who spoke of the early history of the Society, founded in 1841, and of the value of the Harveian lectures which had been delivered annually for the past 50 years. In his response the President quoted some amusing passages from the life of William Harvey, when Harvey was asked to draw up rules for the better management of St. Bartholomew's Hospital. The main improvement Harvey suggested was the complete subservience of the surgeons to the physicians. Sir John Broadbent expressed the hope that members of the Society would support individually the Harvey memorial tower at Hempstead church, and referred to the generous gift which had recently been made to the Society by Dr. George Buckston Browne. Dr. Browne donated £1000, the interest on which was to be used for a £50 prize and medal, to be awarded biennially by the Society. The health of the visitors was pleasantly proposed by Mr. Zachary Cope, to which Sir William Leishman, Sir StClair Thomson, and Sir Edward Marshall-Hall replied. Sir William Leishman, in the course of his reply, paid a tribute to the memory of his old colleague and former president of the Society, Dr. Reginald Dudfield, who died recently. "Few understood," he said, "the value of Dudfield's work both to the State and to the Corps with which he served." Sir StClair Thomson entertained the company, and Sir Edward Marshall-Hall spoke reminiscently, prophetically, and convincingly.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 10TH.

Wages in Clinical Thermometer Industry.

Colonel DAY asked the Minister of Labour whether he was aware that in the clinical thermometer industry male workers of full age were being paid wages which averaged less than £2 for a full working week of from 48 to 60 hours; and was he prepared to accede to the request of the workers employed in that industry for the establishment of a trade board.—Mr. BETTERTON (Parliamentary Secretary to the Ministry of Labour) replied: An inquiry was recently made into the earnings in this trade. The report of the inquiry is at present under consideration, and I am not yet in a position to say what action will be taken.

Advertisements on Vaccination Notices.

Mr. ROBERT MORRISON asked the Minister of Health if he was aware that soap advertisements were printed upon the back of the notice of the requirements of vaccination; what amount was derived from this source; and whether it was intended to continue this means of raising revenue.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part of the question is in the affirmative, and to the last part in the negative. As regards the second part, the amount received for the sale of the advertising space in the current issue of the notice was £135.

Supplies of Liquid and Dried Milk in Local Areas.

Mr. GROVES asked the Minister of Health the quantity and money value of liquid and dried milk supplied to mothers and children during the quarter ended March 31st, 1924, in the county borough of West Ham, the borough of Poplar, the city of Birmingham, and the country generally.—Sir KINGSLEY WOOD replied: The following statement contains the information asked for as regards the three local areas mentioned in the question:—

	Quantity.	Money value.		
		£	s.	d.
West Ham	Dried milk, 61,625 lb.	2750	0	0*
	Liquid milk		—	
Poplar	Dried milk, 3733 lb.	279	19	6†
	Liquid milk, 139,974 pints	1950	3	5
Birmingham	Dried milk, 17,772 lb.	1222	0	0‡
	Liquid milk		—	

* Includes the sum of £1,596 9s. 2d. paid by recipients.
† Includes the sum of £194 17s. paid by recipients.
‡ Amount paid for dried milk supplied at cost price.

The information desired as regards the country generally is not available, but for the financial year 1923–24 the estimated gross expenditure of local authorities in England and Wales on milk supplied to mothers and children was £383,878, and the estimated net expenditure was £174,089.

Putative Fathers and Maintenance Expenses.

Major STEEL asked the Minister of Health whether he would consider the advisability of giving power to boards of guardians to take legal proceedings, prior to the birth of a child, against the putative father of an illegitimate child for payment of the cost of maintenance of the woman during such time as she should be in the Poor-law institution before the birth of the child and for the expenses of her confinement.—Mr. NEVILLE CHAMBERLAIN replied: The Government are not in a position to undertake legislation of the kind suggested at the present time.

Small-pox in Nigeria.

Mr. COMPTON asked the Secretary of State for the Colonies whether vaccination was compulsory in Nigeria; if so, at what age or ages; and how many deaths from small-pox had been reported in the territory in question during the last 10 years for which the figures were available.—Mr. AMERY replied: Under Chapter 53 of the Laws of Nigeria every person in the colony or southern provinces is liable to be vaccinated, and the parents of any child are required to bring it for vaccination within three months of birth. In the northern provinces similar provisions may be made by Orders relating to particular areas from time to time when considered necessary owing to the occurrence of small-pox. It is not possible, however, to enforce the Ordinance strictly, and the number of vaccinations performed between 1913 and 1923 amounts only to 1,890,237 in a population of over 18,000,000. As registration of deaths is not and cannot be made compulsory it is not possible to give any figures which would indicate even approximately the number of deaths from small-pox. The numbers who died in hospital from this disease in recent years are: 1919, 30; 1920, 341;

1921, 182; 1922, 97; and 1923, 44. But it is known that these figures bear no relation to the total mortality.

THURSDAY, JUNE 11TH.

Medical Examination of Persons Charged with being Drunk.

Colonel **DAY** asked the Home Secretary whether his attention had been drawn to a police regulation which did not permit of a person in custody on a charge of being drunk whilst in charge of a motor car being examined by a doctor called by any person other than the person so charged; was he aware that in the case of the Commissioner of Police *v.* Maloney, heard before Mr. St. John Morrow, at the West Ham police court on May 13th, attention to this matter was drawn by the learned magistrate; and whether the regulations now in force would be amended to allow a person charged to be examined under such circumstances by a duly qualified medical practitioner, if so desired by the friends or relatives of such person.—Sir **WILLIAM JOYNSON-HICKS** replied: I understand that the regulations were framed in their existing form after very careful consideration, but I am looking into the whole question in the light of the particular case to which the hon. Member has been good enough to call my attention.

Invalids and Street Noises.

Mr. **JOHN BECKETT** asked the Home Secretary if he was aware of the annoyance to people with children and to invalids of noisy sports, motor cycles and cars being perpetually ridden up and down residential streets; and whether the police were empowered and instructed to deal with this annoyance.—Sir **WILLIAM JOYNSON-HICKS** replied: Yes, Sir. The police are doing what they can to deal with this matter. During 1924, 4774 persons were prosecuted in the metropolitan police district for using inefficient silencers, and there were 4371 convictions. For the first five months of this year there have been 1593 similar prosecutions.

Contributory Pensioners and Medical Benefit.

Mr. **RHYS DAVIES** asked the Minister of Health whether, under the widows', orphans', and old age pension contributory scheme, a person insured under the National Health Insurance Acts would be entitled after reaching the age of 65 years to receive medical benefit and/or additional benefits either in cash or kind.—Mr. **NEVILLE CHAMBERLAIN** replied: The existing position with regard to benefits under the National Health Insurance Act is not affected by the provisions of the Bill before Jan. 2nd, 1928. As from Jan. 2nd, 1928, members of an approved society will be entitled, after they attain the age of 65, to medical benefit and to any non-cash additional benefits provided by the society, but they will not be entitled to any additional benefits payable in cash.

Maternity Centres and Birth Control.

Mr. **THURTLE** asked the Minister of Health if he had received a copy of a resolution recently passed by a conference of labour women asking that medical officers of maternity centres should be allowed to give information on birth control to married women who desired it; and whether he was now prepared to accede to the request contained in the resolution.—Mr. **NEVILLE CHAMBERLAIN** replied: The answer to the first part of the question is in the affirmative. As regards the second part, I am in agreement with the views of my predecessors that institutions provided at the cost of public funds should not be used for so controversial a purpose without express directions from Parliament. In the case of women attending maternity or infant welfare centres who, on medical grounds, appear to need such information as is mentioned in the question, my view is that these cases should be referred to a private doctor or a hospital.

Mental Defectives in Workhouses.

Mr. **RENNIE SMITH** asked the Minister of Health what were the figures for the years 1914 and 1924 of the mentally defective inmates and the total number of inmates of workhouses.—Mr. **NEVILLE CHAMBERLAIN** replied: The total numbers of persons in receipt of Poor-law relief in Poor-law institutions on Jan. 1st, 1914, and Jan. 1st, 1924, were 248,030 and 203,757. The number of inmates of such institutions on Jan. 1st, 1914, who were insane was 19,965. In addition there was an unknown number of mentally defective persons. The number of mentally defective persons, including insane persons, in receipt of Poor-law relief in such institutions on Jan. 1st, 1924, was 25,207.

MONDAY, JUNE 15TH.

Breeding of Beneficial Parasites.

Mr. **CADOGAN** asked the Secretary of State for the Colonies whether he had any information showing that the experiment of breeding beneficial parasites with a view to fighting insect plagues in our overseas Dominions had proved a success.—Mr. **ORMSBY-GORE** replied: Yes, Sir, I understand from the Director of the Imperial Bureau of Entomology that during the 18 months in which this experiment was being carried out two successful introductions of beneficial parasites were effected—namely, a parasite of the pear-slug which is causing serious damage to orchards in New Zealand, and a parasite which was introduced from Nyasaland into Nigeria with a view to control of *Glossina tachinoides*, a species of tsetse-fly prevalent in Nigeria. Two parasites of the earwig have also been introduced into New Zealand, but owing to difficulties in rearing them in the laboratory there the strains have died out. Unfortunately, this work had to be suspended, but it is hoped to resume it shortly.

Venereal Disease in the Straits Settlements.

Mr. **PETHICK-LAWRENCE** asked the Secretary of State for the Colonies whether the legislative council of the Straits Settlements had submitted to him a draft Bill embodying any of the proposals of the committee appointed to investigate the spread of venereal disease in the Straits Settlements which recommended in favour of the licensing and registration of all brothels by a Government official to be called the Controller, and the submission to a weekly medical examination of all prostitutes; and what action he proposed to take in the matter.—Mr. **ORMSBY-GORE** replied: I have received from the Governor of the Straits Settlements a draft Bill which embodies the proposals of the committee referred to by the hon. Member. The Bill has been under consideration by the Advisory Committee on Social Hygiene, and I am now awaiting their report.

Preservatives in Foodstuffs.

Mr. **WHITELEY** asked the Minister of Health whether the new regulations regarding preservatives in foodstuffs were based on evidence that anyone had ever suffered from boron preservative in food; and, if not, whether he was prepared to withdraw such regulation.—Mr. **N. CHAMBERLAIN** replied: The harmfulness of boron preservatives was thoroughly considered by the departmental committee which inquired into the subject. Their report, to which I would refer the hon. Member, shows that boric acid in small doses has been known to produce ill-effects, and that in continued doses it is likely to impair the health of the consumer.

TUESDAY, JUNE 16TH.

British Soldiers Poisoned at Cologne.

Brigadier-General **BROOKE** asked the Secretary of State for War whether his attention had been called to the poisoning of 40 soldiers of the York and Lancaster Regiment at Cologne, of whom two had died; to what food the poisoning was traced; whether this food was supplied by the Navy, Army, and Air Force Institute or by a private contractor; whether any special instructions were issued to Army cooks on the handling of tinned foods, and, if not, whether he would consider the issuing of such instructions to units in future for display in prominent places in all cookhouses; and whether he would lay the result of the court of inquiry at Cologne before the House.—Captain **KING** replied: I am at present awaiting a report on this matter which has been called for; I will communicate further with the hon. and gallant Member as soon as possible. I understand that no soldiers died as a result of the poisoning, and that they were all well again the following day, with the exception of one man, who has now recovered.

An Overdose of Strychnine.

Colonel **DAY** asked the Minister of Health whether his attention had been drawn to a recent case at the Billericay isolation hospital, Essex, where a patient named Joseph Drage died as a result of the administration of an overdose of strychnine by a temporary unqualified nurse; and would he take such action as would allow of only fully qualified nurses being allowed to administer poisonous medicines to patients undergoing hospital or institutional treatment.—Sir **KINGSLEY WOOD** replied: My right hon. friend's attention has been called to this most regrettable occurrence, and he has communicated with the Billericay Rural District Council, to whom the hospital belongs. He has no control over the internal administration of isolation hospitals, but he is informed that the district council are taking all possible steps to prevent the recurrence of such an accident.

THE LATE DR. THOMAS STEVENSON.—The death of Dr. Stevenson took place unexpectedly last week at Dyserth. Dr. Stevenson had served for 30 years on the staff of St. Paul's Eye Hospital, Liverpool, and for many years had been senior surgeon. He took an active interest in the Literary and Philosophical Society, of which he was president-elect. In France, during the war, he held the rank of Lieut.-Colonel in the R.A.M.C. A special memorial service, held in his memory in the Lady Chapel of the cathedral, was largely attended.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, June 23rd.

GENERAL MEETING OF FELLOWS: at 5.30 P.M. Ballot for election to the Fellowship.

Saturday, June 27th.

ANÆSTHETICS: Provincial Meeting in the Physiological Lecture Room, Manchester University.

Discussion on Chloroform, to be opened by Dr. H. P. Fairlie.

Demonstration: Mr. S. R. Wilson and Dr. S. McSwiney (Manchester): Animal Demonstration showing Effects of Adrenalin Injections during Ether and Chloroform Anæsthesia.

Exhibition of apparatus in the laboratories.

Will those wishing to attend kindly apply without delay to Dr. H. R. Phillips, 2, Cumberland Mansions, Bryanston-square, W.

MEDICO-LEGAL SOCIETY.

TUESDAY, June 23rd.—8.30 P.M., Annual General Meeting at the Royal Society of Medicine, 1, Wimpole-street, W. *Business:* 1. Election of Officers and Council for Session 1925-26. 2. Report of the Hon. Secretaries presented to and adopted by the Council. 3. Report of the Hon. Treasurer and presentation of accounts.

After the Meeting there will be a discussion on a Report, made by a Committee to the Council of the Society dealing with the foundation in London of a Medico-Legal Institute.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 22nd, to SATURDAY, June 27th.—WEST LECTURE HALL, Royal Society of Medicine, 1, Wimpole-street. Lecture arranged by the Fellowship of Medicine and open to all members of the medical profession. At 5.30, Dr. A. F. Hurst on The Treatment of Cholecystitis and the Prevention of Gall-stones. Friday, June 26th, LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Course in Medicine, Surgery, and the Special Departments for general practitioners and others. Afternoons only, 4.30 to 6 daily. Clinical demonstrations for one hour and a lecture for half an hour.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Post-graduate Course in Gynæcology. Lectures and demonstrations daily. Operations, pathological demonstrations. Third week.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh Gardens, N.W. Tuesday and Thursday at 2. Lecture-demonstration by Dr. P. Manson-Bahr and Dr. G. C. Low.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square. Daily demonstrations in the O.P. Departments. Bi-weekly lectures by Dr. Roxburgh and Dr. Dore.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Comprehensive Course. Daily out-patient instruction and lectures dealing with the diagnosis and treatment of V.D.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, June 22nd.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases 3 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients.

FRIDAY.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, June 23rd.—4.30 P.M., Dr. F. G. Crookshank: The Sympathetic Nervous System.

FRIDAY.—4.30 P.M., Dr. F. L. Provis: Gonorrhœa in Women.

Daily: Medical and Surgical Clinics, Clinics in the various Special Departments, Surgical Operations, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY–JUNE.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, June 22nd.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., The Diagnosis of Cerebral Tumours: Dr. Riddoch.

TUESDAY, June 23rd.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Compression Paraplegia: (2) Intra-medullary: Dr. Grainger Stewart.

THURSDAY, June 25th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Localisation in the Cerebellum: Dr. Gordon Holmes.

FRIDAY, June 26th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of Spinal Cord: Mr. Percy Sargent.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

MONDAY, June 22nd.—12 noon, The Neuroglia: Dr. J. G. Greenfield.

A COURSE OF CLINICAL DEMONSTRATIONS will be given by Dr. H. J. Macbride, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M. on Tuesdays and Fridays. The Fee for this Course is £2 2*s.*

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. GREENFIELD, Dean of Medical School.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C. 2.

TUESDAY, June 23rd.—5 P.M., Dr. Roxburgh: Psoriasis.

THURSDAY.—5 P.M., Dr. Dore: Animal Parasites.

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-st., W.C.

THURSDAY, June 25th.—4 P.M., Mr. Tyrrell Gray: Intussusception.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

THURSDAY, June 25th.—5 P.M., Mr. L. C. Rivett: Mechanical Difficulties in Labour.

THE JAMES MACKENZIE INSTITUTE FOR CHEMICAL RESEARCH, St. Andrews.

MONDAY, June 22nd.—10.45 A.M., Dr. Orr: Angina Pectoris. 12 noon, Dr. Hynd: Clinical Examination of Urine. 4.30 P.M. (at the Bute Medical Buildings), Prof. Waterston: Structure and Development of the Heart.

TUESDAY.—10.45 A.M., Dr. M. Ramsay: Ocular Manifestations of Vascular Disease. 12 noon, Demonstrations of Electrical Ophthalmoscope. 4 P.M., Dr. Orr: Intermittent Claudication.

WEDNESDAY.—10.45 A.M., Dr. Bryson: Shoulder Pain. 12 noon (at the Bute Medical Buildings), Prof. Waterston: The Sympathetic System in Relation to Muscle. 4 P.M., Prof. Herring: Internal Secretions.

THURSDAY.—10.45 A.M., Dr. Rowland: Albuminuria in Childhood. 12 noon, Dr. Hynd: The Nature of Urinary Protein. 4 P.M. (at the Royal Infirmary, Dundee), Prof. Price: Clinical Demonstration.

FRIDAY.—10.45 A.M., Dr. Paton: Observations on School-children. 12 noon, Dr. Bryson: Mental States in Disease. 4 P.M., Concluding Address.

Appointments.

DICKSON, AGNES F., M.B., Ch.B. Glasg., has been appointed Resident Medical Superintendent at Darnley Hospital, Renfrewshire, and Assistant Medical Officer in connexion with Maternity Service and Child Welfare Work in the County.

MADDEN, FRANK COLE, O.B.E., M.B., B.S. Melb., F.R.C.S. Eng., Emeritus Professor of Surgery in the Royal School of Medicine, Cairo, and Consulting Surgeon to Kasr-el-Ainy Hospital.

WILKINSON, A. GEDEN., M.B., Ch.B. Manch., D.P.H., D.T.M., Part-time Medical Officer of Health for the Egham Urban District.

Metropolitan Hospital, Kingsland-road, E.: MCCULLAGH, W. McK. H., M.B., B.Ch. Belf., F.R.C.S. Eng., Surgeon for Diseases of Women; and WHITE, C., M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng., Consulting Surgeon.

Middlesex Hospital: COCKAYNE, E. A., M.D. Oxf., F.R.C.P. Lond., Physician; and BOLDERO, H. E. A., M.B., B.Ch. Oxf., M.R.C.P. Lond., Assistant Physician.

Queen Charlotte's Maternity Hospital: SAUNDERS, R. M., M.B., Ch.B., Senior Resident Medical Officer; and HAMILTON, G. E. R., M.B., B.S., Assistant Resident Medical Officer.

Certifying Surgeons under the Factory and Workshop Acts: ASHTON, D. A., M.B., Ch.B. Manch. (Yaxley, Huntingdon); MACCORMACK, C. P. V., L.R.C.P. & S. Irel. (Calvert, Buckingham).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Second Asst. in Pathology. £250 12*s.*

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. at rate of £140.

Birmingham, City Mental Hospital.—Asst. M.O. £350.

Birmingham Public Health Dept. (Tuberculosis Section).—Asst. Tuberculosis and Sanatorium Officer at rate of £500.

Birmingham and Midland Hospital for Skin, &c.—Hon. S.

Blackburn and East Lancashire Royal Infirmary.—Third H.S. £150.

Bradford Royal Infirmary.—Res. Surg. O. £250.

Cambridge, Addenbrooke's Hospital.—H.S. at rate of £130.

Chester Royal Infirmary.—Asst. H.S. £150.

City of London Hospital for Dis. of Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. at rate of £100.

Glamorgan County Council.—Dental S. £500.

Gordon Hospital, Vauxhall Bridge-road, S.W.—Res. H.S. at rate of £75.

Great Yarmouth Hospital.—H.S. at rate of £150.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. for six months. £50.

Ilford Urban District Council.—Asst. M.O.H. £600.

King's College for Women, Household and Social Science Dept., Campden Hill-road, W.—Asst. Lecturer in Hygiene. £200.

Lanchester Rural District Council, &c.—M.O.H. £800.

Leicester Royal Infirmary.—H.S. at rate of £125.

Manchester, Ancoats Hospital.—Res. S.O. £200. Also H.S. at rate of £100.

Maudsley Hospital, Denmark Hill, S.E.—Asst. M.O. About £440.

Metropolitan Asylums Board, Mental Hospitals Service.—Jun. Asst. M.O. £500.

National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P.

Newcastle-on-Tyne, Royal Victoria Infirmary.—Hon. Asst. S.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. at rate of £250.

Sheffield, Winter-street Hospital.—Jun. Asst. Tub. O. £250.

Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.

Sunderland Royal Infirmary and Children's Hospital.—Hon. S. for Nose, Throat, and Ear work.

Surrey County Council.—Asst. M.O.'s in Pub. Health Dept. £600.

West Bromwich and District Hospital.—Res. Asst. H.S. £180.

Willesden General Hospital, Harlesden-road, N.W.—Vacancy on Hon. Med. Staff.

Winchester, Royal Hampshire County Hospital.—H.P. £150.

Births, Marriages, and Deaths.

BIRTHS.

Briggs.—On June 10th, at Hawes Hill Farm, Holyport, Berks, the wife of Percy J. Briggs, M.R.C.S., of a daughter.

Campbell.—On June 12th, at Pope's Grove, Twickenham, the wife of Dr. J. M. H. Campbell, of a daughter.

Derham-Reid.—On June 13th, at Auchinellan, St. Helens-road, Bolton-le-Moors, the wife of James Derham-Reid, *M.C.*, M.R.C.S. Eng., L.R.C.P. Lond., Maj. R.A.M.C.T. (ret.) of a daughter.

Paul.—On June 12th, at Tate-road, Sutton, Surrey, the wife of D. H. Paul, M.D., of a daughter.

Robertson.—On June 8th, at a nursing home, the wife of Dr. R. K. Robertson, Brocco Bank, Sheffield, of a daughter.

MARRIAGES.

Ainscow—Siddeley.—On June 11th, at St. Nicholas Church, Kenilworth, Warwickshire, James Arthur Ainscow, M.B., Ch.B., to Nancy Mabel Mercer, elder daughter of Mr. J. Davenport Siddeley and Mrs. Siddeley, of Crackley Hall, Kenilworth.

Gathergood—Batho.—On June 9th, at St. Andrew Undershaft, St. Mary Axe, E.C., Leslie Somerville Gathergood, M.A., M.D. Camb., to Madeline, only daughter of Mr. Alderman and Mrs. Batho, of Summit House, Frinton-on-Sea, Essex.

Heath—Collier.—On June 6th, at the Brompton Oratory, William Powell Heath, of Nottingham, second son of the late Mr. and Mrs. T. H. Heath, of Crewe, Cheshire, to Isabel Martha Collier, M.B., M.R.C.S., youngest daughter of Mr. and Mrs. John Collier, of Sefton Park, Liverpool.

Hewer—Champney.—On June 10th, at Bristol, Christopher Langton-Hewer, M.B., B.S., to Doris Phœbe, youngest daughter of Mr. and Mrs. D'Arcy Champney, of Bristol.

Yates—Fagge.—On June 10th, at St. Marylebone Church, Henry Yates, M.A., M.B., B.Ch., to Florence Dora, second daughter of Mr. and Mrs. C. H. Fagge, of Devonshire-place.

DEATHS.

Aitken.—On June 11th, at Portland-road, N., David William Aitken, M.B., C.M.Edin. (late of Edinburgh).

Clippingdale.—On June 6th, Samuel Dodd Clippingdale, F.R.C.S. Eng., M.D. Aberd., late of Holland Park-avenue.

Ferguson.—On June 8th, at Edinburgh, Edward Ferguson, Fleet Surgeon, Royal Navy (retired), in his 74th year.

Price.—On June 13th, at Wellington-square, Chelsea, Major-General William S. M. Price, late A.M.S., aged 81.

Williamson.—On June 6th, at a London nursing home, Emma, the dearly-beloved wife of R. T. Williamson, M.D., F.R.C.P., of Barnes, London, S.W. (formerly of Manchester), aged 55

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

FRUIT AND VEGETABLES IN LONDON.

An outdoor Chadwick lecture on the Sources of the Fruit and Vegetable Supply of London was given by Sir A. Daniel Hall, F.R.S., at the Chelsea Physic Garden on June 11th, when Sir William J. Collins presided. London, said the lecturer, owed its earlier supplies of fruit and vegetables to the settlement of refugees from Flanders and France—e.g., Richard Harrys, fruiterer to King Henry VIII. made an orchard at Teynham, Kent, with "plantes from beyond the seas" and this became the "chief mother of all the orchards"—the old market gardens and orchards of Kent, Middlesex, and Surrey on the "brick earth" deposits of the Thames valley. To-day supplies are drawn from world-wide sources. Apples can be bought the whole year round, although English apples are only in season in August, September, and October. The first early cherries coming from France round Angers get people into the way of eating cherries by the time English cherries are ready. Strawberries will not travel overseas; the only strawberries coming from any distance are brought from the Clyde valley some four to six weeks later than the main crop varieties. Of the 8 million hundredweight of oranges imported into England in 1923, 6½ million came from Spain. Much development of orange-growing is going on in Palestine, whence comes the Jaffa orange, and in South Africa and Australia, in those places where irrigation water is available. Nearly 1 million hundredweight of lemons come from Spain and Italy. Some 12 million bunches of bananas reach this country from Canary Islands, West Indies, and Central America.

Potatoes and Greens.

We are practically self-supporting as regards the 3 million hundredweight potatoes consumed; only 5 per cent. of the supply are imported. The first potatoes on the market come from the Canary Islands, especially Teneriffe, Spain, Egypt, and Malta. The earliest English arrive in May from the Scilly Islands, followed shortly by supplies from Penzance and Jersey, succeeded very quickly by those from near St. Malo and the Ayrshire coast near Girvan. The London main crop of potatoes comes chiefly from Lincolnshire, the Fens, Kent, and the Lothians. The "top of the market" is attained by the Dunbar red, a potato grown in the light red-coloured soil round Dunbar; no matter how often it is reheated it retains a white colour, an important characteristic of a potato to be consumed possibly after numerous reheatings in a restaurant. The growing of tomatoes has now become very largely an English trade; of the 3000 acres of glass in the Lea valley near Cheshunt half is devoted to tomato-growing; the best grower can produce 40 tons to the acre. In 1923 the Canaries sent over a million hundredweight between October and August, the Channel Islands half that quantity between April and December, Holland rather less between May and November. The chief centres of green vegetable production are North Kent, Middlesex, Essex, Bedford, Huntingdon, Worcester, and Wisbech. The Penzance broccoli is in serious competition from Roscoff area with its better packing. Other cauliflowers are received from Italy and St. Malo.

Distribution.

The lecturer next referred to the London wholesale markets, Covent Garden, the Borough, and Spitalfields—which are largely potato markets—Stratford and Brentford, and their methods of doing business. He described how Covent Garden acted as distributing agent to provincial markets. The produce unfortunately passes through the hands of a long chain of persons between the grower and the consumer; the grower sells to a commission agent, who sells to a London wholesale dealer, whose goods are bought by a commission buyer to sell to the retailer; the result is that a cabbage for which the grower gets 1*d.* costs the consumer 6*d.* Nothing but hammering away at the problem will secure fair play for the producer and the consumer.

Sir William Collins, in thanking the lecturer, referred to the undesirability of vegetarianism; Sir James Crichton-Browne to the great value of spinach as a source of vitamins.

Demonstration of Preservative Methods.

After the lecture the audience looked at the exhibit intended to demonstrate methods of preservation of fruit and vegetables displayed by the Chipping Campden (Glos.) Research Station of the University of Bristol, where ten-day courses of instruction are given in this subject. On a table were set out jam made from plums preserved in sulphur dioxide, blackberry and loganberry syrup, bottled carrots, peas, and runner beans, macedoine of vegetables, tomato chutney, and tomato ketchup. The lady demonstrator showed how to seal a tin with the Campden canner. If able to obtain the use of this sealer, which does away with the expense and trouble of using solder, the housewife and small fruit-grower will be able to can fruits and make a profit. It is hoped that women's institutes will provide themselves with a sealer for the general use of their members. Tins can be obtained by writing to the Research Station ; those to hold a reputed pound cost about 1½*d.* ; the 2 lb. tins 2½*d.*, while the corresponding price for the 2 lb. glass jar is 11*d.* or 11½*d.* It is understood that some small fruit-growers who started canning fruit have given up as they could not get hold of tins at a reasonable price, while the cost of glass jars was prohibitive.

Standardised Packing.

At the other end of the table was a display of packages used for fruit and vegetables. It included a French lettuce crate (non-returnable), a tomato box (non-returnable), which has largely replaced the "strike" and the 12 lb. handled basket ; a 2 lb. (returnable) box for English forced strawberries, and a melon "handle" for Guernsey melons. Packages of this type are recommended by the Ministry of Agriculture. If the grower will (1) use a standardised package which enables the articles to be packed so as to avoid injury, and to be displayed and at the same time handled by market porters, &c. ; (2) pack an honest package of goods of a certain standard of quality, he will be allowed to affix to the packet a label issued by the Ministry which serves as a guarantee of quality. Until recently the home grower has been able to dispose of his goods round the corner ; foreign growers who grow for export have paid attention to methods of presentation of the articles so successfully that English growers have failed to sell their goods in competition. The Ministry have been obliged to provide instruction at Penzance to prevent the local trade being entirely captured by Roscoff. Non-returnable packages must be in a form convenient for the use of the housewife who gets a better article if she buys it as it leaves the grower ; the wholesaler or retailer does not want to break bulk or damage the articles.

In this country with its variable climate gluts of fruit are unavoidable. The Ministry intend using broadcasting to inform the housewife of an approaching glut some three weeks or so beforehand, so that she can make the preparations necessary and assemble the tins, jars or bottles required. A plum glut, for instance, only lasts a week, giving no time for preparation. In leaflet No. 2 of the Research Station a method of weighing jam during its boiling is described whereby the inexperienced may be able to tell when the jam is sufficiently boiled to set when cool and to keep well.

THE NEED FOR MORE AMBULANCES.

AT a recent inquest in Southwark, the coroner, Dr. F. J. Waldo, again called attention to the need for more ambulances in the metropolitan area, if cruel and dangerous delay is to be avoided in the conveyance of street accidents and other urgent cases to the nearest hospital. On the occasion in question a man, 71 years of age, had slipped on a banana skin, and in falling had sustained a simple fracture of one of his thighs, in consequence of which he died. The evidence further showed that he lay on the pavement for more than a quarter of an hour before he was removed. An ambulance arrived 14 minutes after it was first summoned, the delay being due to it having been sent for to pick up another accident case, and this one ambulance was proved to have dealt at that time with five cases in 50 minutes. Incidentally, the policeman who was called to the accident had been in the force for five years but had not attended any course of instruction in first-aid under the St. John Ambulance Association, nor did he exhibit any desire to do so. A verdict of "Accidental death" was returned by the coroner, and the following observations are based upon those made by Dr. Waldo in the course of the inquest and upon the facts proved in the evidence before him. (1) The number of accidents in the streets of London has greatly increased in recent years, and a large proportion of these is caused by motor-driven vehicles. (2) The number of motor cars and other motor-driven vehicles has increased and is increasing rapidly, and there is every prospect of the increase being continued. (3) This points to a constant increase of accidents not only because there will be more motor vehicles, but because the increase in their numbers, and particularly in the number of fast-driven cars and lorries, means the constant influx of inexperienced, and often untrained, drivers. (4) The present number of motor ambulances in the metropolitan district ruled by the London County Council, as distinct from the City, is 11, with a prospect of three more by the end of the year. It is submitted that even then 14 will not be sufficient to deal with the emergencies which must occur. It is not only a question of providing for accidents on their present scale, but for an almost inevitably greater number of them. (5) It has been suggested[1] that the coöperation of the St. John Ambulance Association and of the Metropolitan Asylums Board with the L.C.C. would be of use in ensuring an efficient service, but as far as we are aware no definite alliance for this purpose between these bodies has been effected. (6) A suggestion that ambulances might be housed at fire stations has also been made. At the inquest before Dr. Waldo a witness said that this plan has been adopted with success at Portsmouth. No doubt conditions there are different from those in London, but the utilising of fire stations for ambulances has been condemned by the metropolitan authorities as impracticable, without any convincing reason, so far as we know, having been given to a deeply interested public for the decision. (7) The question of policemen being obliged to take courses of instruction in first-aid is outside that of the provision of ambulances, but we note that Dr. Waldo, who is coroner for the City as well as for Southwark, speaks of the police in the City being obliged to undergo instruction which is optional for police outside its area. This point, presumably, concerns the Home Office. In conclusion, we would point out that when the victim of a street accident has to lie for what seems to sympathetic bystanders an unnecessarily long time waiting for an ambulance, it is inevitable that unfavourable comment, and possibly exaggerated blame, should be directed against the "authorities" in the daily press. In these circumstances the London County Council should feel assured that public opinion will not censure them for extravagance if they should make reasonably ample provision to meet a growing demand.

AN EXHIBITION OF INVENTIONS.

THE exhibition held during the past week at the Central Hall, Westminster, was the first of a series of Annual Public Exhibitions of Inventions organised by the Institute of Patentees. The practical results of the series and of the work of the institute, it is hoped, will be the introduction of legislation beneficial to inventors and a just recognition of their work. The way in which inventors have responded to the new movement may be gauged from the fact that nearly 240 inventions were displayed at the exhibition. Of the ten sections into which the inventions were grouped that consisting of domestic and labour-saving devices was the largest, 20 per cent. of the exhibits being produced by women. Exhibits of particular interest in this section were a milk churn and a window fly screen. The novel feature of the former was the lid, so fixed that the milk was hermetically sealed, whilst the mouth of the churn was protected from dirt during transit operations. The fly screen consisted of a cotton gauze spring blind attached to a sash window so that when the latter was opened the screen unrolled to cover the opening. The display of several excellent devices for the automatic disinfecting and cleansing of sanitary systems was indicative of the thought expended on a matter vital to the public health. An invention of direct medical interest was an artificial pneumothorax apparatus, in which air is compressed by the weight of a piston instead of by the customary hydraulic means. The instrument is strong, simple, and portable. The remaining sections of the exhibition, devoted to inventions in mechanical, electrical and wireless engineering, in building and in toys, appealed to a wide public.

RHEUMATOID ARTHRITIS AND OSTEO-ARTHRITIS.

Dr. Robert B. Osgood, of Boston, U.S.A., delivered the Hugh Owen Thomas Memorial Lecture at Liverpool on June 2nd, taking as his subject the differentiation of the pathology and symptoms of "rheumatoid arthritis" and "osteo-arthritis." The former, he said, was a disease of the first half of life, occurring in toxic subjects of the so-called "ptotic" type and not infrequently ushered in by a definite illness, while the latter developed insidiously in persons otherwise well, for the most part in the latter years of life. The ætiology was discussed in some detail. The rheumatoid series of cases clinically were associated in a few cases with definite foci of infection in teeth, tonsils, pelvis, or elsewhere, and in many more with intestinal stasis due in certain instances to lesions susceptible of surgical treatment. The possibility of infective or toxic origin therefore arose—no specific organism, however, could be incriminated. In many cases no definite focus could be found, and surgical measures were not to be recommended unless a definite lesion was demonstrably causing deterioration of the general health. He found such laxatives as agar-agar, frequent colon lavage, abdominal massage, rest from worry and overwork, and the open-air life much more valuable in the majority of cases.

A fine series of slides was then shown, illustrating bone atrophy and loss of sharp joint outlines as seen by X rays, and a number of pathological sections showing extensive small round-cell infiltration in the synovial membrane and ulceration of cartilage, particular attention being called to the obliterative changes taking place in the smaller arteries. The orthopædic surgeon's first duty, he continued, was the prevention of deformity and the avoidance of friction on the inflamed surfaces. Manipulation could only be done with safety when the condition had become perfectly quiescent and was often useless on account of the tendency to fibrous or even bony ankylosis. Occasionally aspiration might be called for to relieve tension in the acute stage, and the operation of synovectomy offered hopes of some improvement. Arthroplasty in his hands had not given encouraging results. In some cases resection by giving a stable, painless joint was a procedure of great value. In a limited number of cases a pseudo-arthrosis might be recommended, as was done by Sir Robert Jones in the case of the hip-joint.

---

[1] See THE LANCET, Jan. 17th, 1925, p. 141.

Passing to the subject of chronic osteo-arthritis, Dr. Osgood pointed out the importance of the bony overgrowth at the articular margins leading sometimes to locking of the joint, but rarely to true ankylosis. He also alluded to the part played by trauma, especially when the disease developed earlier in life. The treatment here was along different lines. Movement short of pain, all forms of physiotherapy stimulating increased blood-supply, removal of strain within the joint by remedying faulty body mechanics were all important. Attention to the bowels did not give the same dramatic results, sometimes seen in rheumatoid cases, but the diminution of meat, sweets, and foodstuffs liable to increase acid fermentation was found helpful. Apart from the prevention and treatment of contractures surgery had little part to play. Rarely loose bodies formed and called for removal, and occasionally arthrodesis was necessary as being the lesser evil than the pain and disability suffered. Such was specially true of the hip in younger people.

In conclusion, the lecturer made an appeal for closer and heartier coöperation between the general practitioner, the skilled "internist," and the orthopædic surgeon. The part played by personality was very prominent and the man who could win and hold the patient's confidence, he it must be who should be captain of the team.

CHARACTER CHANGE AFTER ENCEPHALITIS LETHARGICA.

IN the *Archives de Médecine Navales* for January, 1925, which is now published quarterly, Surgeon-Commander Dr. P. J. L. Charpentier reports on insanity following encephalitis lethargica, narrating as typical the case of a regulating petty officer, invalided in 1924 from the Red Sea to Toulon Hospital, in which he had been in 1922 a patient convalescent from encephalitis lethargica. After two months' creditable service on board he began to give trouble, and had been rude to, and had even threatened, his superiors. He said he knew he was doing wrong, but he could not stand his life, he could not check his words or actions. He looked healthy, neither pale nor wasted. He had a double internal strabismus, and slight inequality of the pupils, tremor of the upper lip, exaggerated reflexes, and hyperæsthesiæ. Wassermann negative in the cerebro-spinal fluid, lymphocytosis, 1 cell per c.mm., albumin 1 per cent., much sugar. The patient is no fool, he knows what is going on around him, but watches events in order to find occasions of discord. Dr. Charpentier thinks the disease attacks brains weakened by heredity, with resulting unsociability and insubordination.

EXTREME PARASITISM.

As will have been noted by our readers the Psychology of Animals Swallowed Alive was made the subject of a really amusing address at the Royal College of Surgeons of England by the President, on the occasion of the visit to the College of the Inter-State Post-Graduate Assembly of America. The reactions of the swallowed appear to be simple when they can be ascertained. They desire at all costs to get out of prison, and in effecting their escape they sometimes inflict painful death in return for projected murder.

The subject of the address has long interested mankind, and under the impetus given by the story of Jonah in the whale's belly—a story that has its counterpart surely in the annals of many early civilisations—the legends have become many. It is almost unnecessary to say that the lives of the Saints furnish arresting examples. Thus, according to the Benedictine tradition, church music was instituted when Saint Benet and his twin sister, Scholastica, were heard warbling holy psalmody in their mother's womb, and some sort of traditional respect for the Acta Sanctorum must have influenced the authorities of St. George's Hospital less than two centuries ago in their attitude towards the case of Miss Mason. This interesting lady, in 1750–51, spent many months in St. George's Hospital under the care of the most eminent physicians in town. "This girl is no impostor," says a contemporary reporter. (We condense his statement.) "She has been carefully watched. Her belly is swollen to an enormous size and whenever she is touched it emits a kind of croaking noise. audible at a distance of 20 yards. Many suppose that there is a live animal inside her." Here is a definite reference to a common belief which had its origin in a perversion of Christian teaching. It was supposed possible by many for women to become mothers by all kinds of curious sires. Indeed, among the vulgar the belief still lingers, and the sad tale of the alderman's daughter who gave birth to a litter of Newfoundland pups is still repeated, and still if the sceptic asks for details he is told that the matter was at once hushed up in high City circles. An odd case which has its bearing upon the possibility of the human body sustaining a large and highly developed parasite is that of a woman admitted into the wards of St. Bartholomew's Hospital in 1807. After giving birth to a child, she had been seized by an insatiable appetite for food. Her husband could not pay for the amount she required, but in the hospital she was supplied "with three pounds of meat daily, and with a quartern loaf and much liquor." Left without sustenance for one hour, she seems to have suffered agony, uttering shocking cries, for which she would apologise to those about her. On being operated on within a week she was relieved of an enormous creature, said to resemble a toad, which weighed eight pounds. We have here probably a case of bulimia with the details exaggerated, and the journalist who records the case, having committed himself to a theory that only a parasite could account for such hunger, rounded off the story as he would have had it.

SEX-LIMITED BOOKS.

THE anonymous author who had previously written "How to be Healthy" and "For Women Only," received, he tells us, many suggestions for a further addition to this series, and he therefore now produces a book[1] "addressed to the manhood of the nation." He deals in popular language with certain afflictions peculiar to the male sex such as varicocele, enlarged prostate, and stricture; with diseases much more common in men such as arterio-sclerosis and aneurysm; with the subject of venereal diseases, where he shows himself to be an ardent partisan of the immediate disinfection school; and finally with a curious heterogeneous set of subjects such as sleep, neurasthenia, drug habits, circumcision, sterilisation of the unfit, and advice on the treatment of oneself on the morning after a night out. On the whole the book has the accuracy which is of prime importance in books of this nature, but it is startling to find on p. 53 that "an aneurism is purely an affair for an operating surgeon . . . Once it is detected an operation becomes inevitable," without any qualifying remarks as to the site of the lesion.

MERCUROCHROME IN GONORRHŒA.

To the Editor of THE LANCET.

SIR,—As this compound, containing over 20 per cent. of mercury in a non-ionised form, is coming into use, I think it should be made clear that in a footnote to the article by Young, White, and Schwartz (*Jl. A.M.A.*, Nov. 15th, 1919, p. 1491), a grave error or misprint was perpetrated, in that a 25 per cent. solution was advocated as an injection in gonorrhœa, whilst a 2·5 per cent. solution was intended. My firm has devoted attention to the manufacture of this compound in a solid form ready for dissolving, and I have had no adverse reports of its use. In the Extra Pharmacopœia, eighteenth edition, p. 675, I have summarised statements in the current medical literature on this new remedy. The 25 per cent. solution was mentioned, but the strength seemed to me so high as to necessitate a word of warning, which, therefore, I inserted both at that page and in the preface, p. xvii. At a recent meeting at Montreal of the Inter-State Post-Graduate Assembly of America, I understand the mercurial was criticised severely, and it is possible that the strength of the solution is of paramount importance. May I ask that medical men having a copy of the Extra Pharmacopœia will be good enough to note on p. 675 that, in general, solutions should not exceed 1 or 2 per cent. strength. The misprint was pointed out by Dr. White in the *Jl. A.M.A.*, Nov. 29th, 1919, p. 1708, which I have only quite recently seen. It is there stated that the 2·5 per cent. is the strongest solution used in the urethra.

I am, Sir, yours faithfully,

W. H. MARTINDALE.

10, New Cavendish-street, London, W.,
June 9th, 1925.

X.Y.Z.—Others beside Prof. Kristine Bonnevie, of Oslo, have claimed to be able to determine a child's parentage by certain characteristics of finger-prints, but we have seen no evidence that help is to be obtained in this way. The elaborate observations of Dr. Henry Faulds were definitely negative.

A Study
OF THE
TUBERCLE COMPLEMENT-FIXATION REACTION
WITH BESREDKA ANTIGEN IN THE INVESTIGATION OF PULMONARY DISEASES.

By W. BROUGHTON-ALCOCK, M.B. Camb.,
MACKENZIE DOUGLAS, M.D. Edin.,
AND
H. C. LUCEY, M.D. Lond., D.P.H.

(From the Central and Orpington Laboratories, Ministry of Pensions.)

Since the serological reaction as an aid to diagnosis was first applied to tubercle infection by Neisser and Sachs, many workers have investigated the tubercle complement-fixation reaction (T.C.-F.R.). Reference may be made to two recent reviews in which helpful summaries are given.[1 2] The purpose of this paper is to make known the laboratory findings of the T.C.-F.R., employing Besredka's antigen, and their relationship to the findings of the *B. tuberculosis.* We have tabulated the results obtained from the examination of the sputa for *B. tuberculosis* and of the blood sera by the T.C.-F.R., collected from ex-Service subjects as part of a complete routine investigation on each to determine the presence or absence of pulmonary tuberculosis, its activity or arrest. The total number of 6000 were males and include two groups of cases of which approximately two-thirds were examined as out-patients and one-third as in-patients in observation wards. The results in each group were practically similar. We would emphasise that the subjects examined showed various disabilities of a pulmonary nature, due to chest wounds, gassing, pandemic influenza of 1918, chronic bronchitis, &c.; many cases examined were not clinically tuberculous, though a certain number may have been so some years previously or may have more recently developed tuberculosis consequent upon or subsequent to a previous lung condition.

The difficulties and differences of opinion in diagnosis of tuberculosis upon clinical examinations of pulmonary cases, and especially conditions consequent upon gassing or the pandemic influenza of 1918, wherein the X rays reveal pathological changes similar to those found in certain forms of pulmonary tuberculosis, are well known and can be readily understood, so that any practical and reliable aid to specific diagnosis by laboratory methods is a valuable one. Pre-war experience has shown us that for various reasons the *B. tuberculosis* is found in the sputum on repeated examinations in but approximately 40 per cent. of all cases of clinically diagnosed pulmonary tuberculosis, so that further supplementary aids, such as serological investigation, in addition to the search for the organism, have their utility in the same way as they have in certain other microbic infections.

Table I. gives the relationship of results of the T.C.-F.R. when employing Besredka's antigen in cases showing (1) a positive finding of *B. tuberculosis* in the sputum (*a*) at the same date or (*b*) during or after the Great War, or (2) a negative finding at present or past or at both examinations of the sputa. Also is given the percentage of positive Wassermann reactions (W.R.). It is important to have found that a percentage of pulmonary cases under investigation were suffering from lesions due to syphilis. These have benefited by diagnosis and subsequent specific treatment.

Negative Findings.

In Table I. the percentage of negative findings when *B. tuberculosis* was present in the sputum is based on one examination only of the blood. It was not practical to make many repeated examinations, and in the limited number of cases where a second examination was practicable we found some support to the observation, we think first made by Calmette, that tuberculous cases giving a negative T.C.-F.R. at one examination may give a positive finding when re-examined, and a subject giving a negative finding when clinically positive should have the blood-serum re-examined on a further one or more occasions. In this connexion we call attention to Ichok's publication.[2]

May we assume that the specific fixation property detectable in the serum in tubercle infection is dependent on individual response or reaction and that pulmonary disease is an infection of localised activities giving rise to smaller production of this fixation property or so-called antibody than is to be expected and found in other diseases where the infection is at a certain period more generalised. In the generalised tertiary or final stage of tuberculosis the patient is approaching death and natural response and reaction appear limited or absent, so that workers state that the T.C.-F.R. is herein not infrequently negative. In the few (five) cases of whom we have examined the bloods taken at the autopsies which showed death due to generalised tuberculosis, the reaction was, however, positive. In two cases the blood taken six to nine days and in one case the cerebro-spinal fluid taken four days before death, the T.C.-F.R. was positive. In one other case the blood one month before death was negative.

Besredka's experience has shown him that a good antigen of human *B. tuberculosis* alone gives satisfactory results and prefers it to a polyvalent antigen or mixture of human and bovine strains. Accepting

* Information based chiefly on ex-soldiers' statements: whenever possible on documentary evidence.
† When documentary evidence was obtainable. B.L. = Border-line.

(*a*) Seven of these cases were examined on one, two, or three subsequent occasions at intervals of several weeks or months with a view to ascertaining whether sufficient tuberculous antibody appears at certain periods to cause a positive complement-fixation reaction. Four maintained negative reactions throughout, though *B. tuberculosis* was again found in sputa. One case on second examination gave a weak positive reaction, one case on second examination gave a border-line reaction, and one case on third examination gave a weak positive reaction.

this, we think that were it practicable, by the use of autogenous strains, the percentage of negative findings in tuberculous cases may, and, reasoning from experience of other specific antigen-antibody C.-F. reactions, would probably be reduced. Our tests with autogenous strains have been too few to enable us to form a judgment.

Positive Findings.

The percentage of positive findings when *B. tuberculosis* is found in the sputum is 84·5 per cent., that of doubtful reactions 6·1 per cent., and of negative 9·4 per cent. Regarding the positive findings of the T.C.-F.R. when *B. tuberculosis* has been found previously, it is not possible for us to state for how long the reaction remains positive after the arrest of active diseases. Besredka estimates the persistence may be up to six months.

To consider the case giving a positive T.C.-F.R. finding when there is no evidence of tuberculous lesions on clinical, X ray, or sputum examinations, these are grouped into two categories: (1) when the W.R. is also positive and (2) when the W.R. is negative.

Group 1.—The incidence of the finding of *B. tuberculosis* in positive W.R. cases is shown. That the two diseases occur concurrently, though known, is supported by our figures; but our percentage of positive W.R. which bear close relation with that found at general hospitals in series of unselected cases does not indicate that tubercle is more common in the syphilitic. Of the 246 ex-Service men in whom *B. tuberculosis* was found 36, or 9·6 per cent., gave a positive W.R. That a positive W.R. is not due to tubercle infection has been amply confirmed, but we share the opinion of the early French workers that a non-specific positive T.C.-F.R. is not infrequently found when the W.R. is positive and when Besredka's antigen, which includes the culture-media, is employed.

Group 2.—Where the W.R. is negative and T.C.-F.R. positive and there is no evidence of tuberculosis by clinical or by other laboratory methods of examination, questions are raised which cannot at present be answered by experiment. A prolonged research and keeping of the subjects under investigation can best help in the elucidation of these questions. In our routine procedure we have had a few cases which were clinically non-tuberculous and gave a negative sputum finding and positive T.C.-F.R. and which, returning 6 to 12 months later for re-examination, gave a positive sputum finding. There are, one is aware, a few cases which are not detected clinically, nor by X ray examination. Again, there are cases with subjective symptoms, sometimes classified as latent tuberculosis, which may be cited in explanation of these positive T.C.-F.R. findings. Still we are faced with the fact that a percentage of cases give a positive T.C.-F.R. in the absence, past or present, of the findings of the *B. tuberculosis* or of clinical evidence of tuberculosis of the lungs or other tissues. What gives rise to this positive finding, which is not without analogy in the serological investigations of other infections and the employment of the specific antigen antibody complex? Diphtheria has been cited as a disease so doing, since sera of some patients having received anti-diphtheritic sera gave a non-specific T.C.-F.R. Do also other infections? Willmore[3] found that a generalised, and we that a pulmonary, infection due to species of the closely related streptothrix group gave a positive T-C.-F.R. finding in each case. Also we have to consider the action of constituents or properties in certain sera to combine with the non-specific protein and lipoid colloids in the antigen used.

Doubtful Results.

Those familiar with the delicacy of the complement-fixation reaction of the specific antigen-antibody complex, will appreciate the difficulty that occasionally arises in reading and interpreting results, and we have thought that in compiling our findings it would be more instructive to class the so-called border-line reactions separately. It will be noted that such results occur in all groups, including cases wherein the tubercle bacillus is found at the time of examination with and without clinical evidence of disease, so that the finding cannot be classified as a negative one.

Conclusions.

And now to the significance of these findings and values to be assigned.

Let us introduce our remarks by the wise counsel —Look to the laboratory for aid, not responsibility for diagnosis in clinical medicine. Our principal object is to provide reliable additional evidence to the clinician in the not infrequent difficulties of diagnosis of tuberculosis. Any survey must be on the basic foundation that the living organism is not a machine nor can the chemico-physical activities in the body regulating organic function be brought to manifest themselves in test-tube experiment with mathematical precision of result and facility of interpretation. Progress has come from experiment since and through work upon Koch's original tuberculin test, von Pirquet's skin test, Wright's opsonic index, Neisser and Sachs's, Besredka's, Inman's and Dudgeon's work (amongst others) on the tubercle C.-F.R. Prof. H. R. Dean gave at the 1923 meeting of the British Medical Association a paper stimulating to discussion, and we hesitate to criticise. We cannot, however, admit comparison of the readings and interpretations in opsonic index and C.-F.R., nor that the work of the C.-F.R. has been disappointing, at least in its service to the practitioner. We are optimistic in our view of the development of a still more useful reaction as progress is made, in preparation of the antigen, in our understanding of the rationale of the reaction, and in our knowledge of the pitfalls or non-specific reactions as well as of the findings in the varied stages or extent of the disease and of the response to the two groups of causal organisms with their number of strains. One practical advantage not to be overlooked is, that the T.C.-F.R. can be applied in an out-patient clinic.

Alongside the T.C.-F.R. let us consider the better-known W.R.: what modification it has undergone since Wassermann's original method was published. Workers throughout the world have aided in its simplification and modification, and only in few isolated laboratories does one now see the original technique and employment of a specific antigen and they have determined its great but relative value. A negative W.R. of the blood may be found in a syphilitic infection, and a positive W.R. has been found in other than *S. pallida* infections. To find a blood serum giving a W.R. positive is not per se a diagnosis of active syphilitic infection nor of the assured appearance of a tertiary sign or symptom, nor to find it negative sufficient proof of the entire absence of this disease. But who would dispute the invaluable aid to clinical medicine the W.R. is? Again, let us consider heterologous serological findings. We have seen cases of Malta fever with antibody in the serum binding itself to a high degree with *V. choleræ* and agglutinating it, and the converse holds as first shown by one of us. There is also the well-known example of the agglutination of *B. proteus* by sera of cases of typhus. It may be that in the T.C.-F.R. the tubercle antigen fixes other antibodies in addition to those arising in certain diphtheria cases receiving antitoxin and some streptothrix infections, which have not yet been determined.

At this stage of investigation we consider that the results of the test should carry some weight with the clinical observer and when a positive finding is recorded a very full investigation should be made before ruling out an infection of tuberculosis, a disease of such protean signs and symptoms. The margin of error of negative findings in bacteriologically positive cases is just under 10 per cent. on one examination of the blood, probably less on repeated examinations. As in other serological reactions one cannot expect more of it than a valuable link in the chain of evidence. When Besredka's antigen is used a W.R. should also be carried out.

Technique.

Tubes.—3 in. × ½ in. are used. These are extra wide to allow of easy mixing of the constituents when the tubes are shaken.

Racks which fit Harrison's water-bath are used, but to admit the wider tubes the holes must be increased to a diameter of ⅝ in. A rack will hold 40 holes of this diameter.

Antigen.—Unit used is 0·3 c.cm. of Besredka's undiluted antigen.

Hæmolytic System.—3 per cent. suspension of sheep's red cells, each c.cm. of which is sensitised with 8 M.H.D. of hæmolytic serum. The quantity of 3 per cent. cells used for each tube is 0·5 c.cm. plus 0·5 c.cm. of saline dilution of the hæmolytic serum, so that each tube actually receives 1 c.cm. of a 1·5 per cent. suspension of sensitised cells.

Complement.—Guinea-pig, killed the previous afternoon. The blood is placed in incubator at 37° C. for one hour to facilitate separation of serum from clot, then in ice-chest overnight. The serum is pipetted off next morning. A preliminary estimation of the M.H.D. of complement is made on the same day as the test, and at the same time the amount of complement fixed during two hours by the unit of antigen (0·3 c.cm.) used in the test, is estimated. For these estimations two rows of eight tubes are put up as shown in Table II.

TABLE II.

Front Row for Estimation of M.H.D. of Complement.

1/15 comp. ..	0·06	0·08	0·1	0·12	0·14	0·16	0·18	0·2
Saline	0·94	0·92	0·9	0·88	0·86	0·84	0·82	0·8

Back Row for Estimation of Amount of Complement Fixed by Unit of Antigen.

1/15 comp. ..	0·1	0·12	0·14	0·16	0·18	0·2	0·22	0·24
Antigen . ..	0·3	0·3	0·3	0·3	0·3	0·3	0·3	0·3
Saline	0·6	0·58	0·56	0·54	0·52	0·5	0·48	0·46

The total volume in each tube is 1 c.cm.

Both sets of tubes are allowed to stand at room temperature for one hour and then put in the water-bath at 37° C. for another hour, at the end of which time 1 c.cm. of sensitised cells is added to each tube (making total volume to 2 c.cm.) and the tubes are shaken. The results are read after half an hour at 37° C. and 15 minutes at laboratory temperature. The tube in the front row, which shows *complete* hæmolysis with the smallest amount of complement, is noted. This amount of complement is the M.H.D.

The tube in the back row, which shows *complete* hæmolysis with the smallest amount of complement, is also noted. The difference between the amounts of complement contained in these two tubes is the amount of complement fixed by the antigen. For example, say the fifth tube of the front row (containing 0·14 c.cm. of 1/15 complement) and the sixth tube of the back row (containing 0·2 c.cm. of 1/15 complement) are the two tubes chosen, then the M.H.D. is 0·14 c.cm., and the amount of complement fixed by antigen is 0·2 – 0·14 = 0·06 c.cm.

Test.—Six tubes are used for each serum. These are placed along the length of the rack, leaving a space between the first two and the last four tubes. 0·2 c.cm. of inactivated serum is added to each tube. The first two tubes are for serum controls and the last four for the test proper. To the first control tube is added 1½ M.H.D.'s of complement. To the second control tube is added 1½ M.H.D.'s of complement plus the amount of complement fixed by antigen. To the first, second, third, and fourth tubes respectively of the test proper are added 1½, 2, 2½, and 3 M.H.D.'s of complement, plus the amount of complement fixed by antigen. These graduated amounts of complement are conveniently contained in a volume of 0·5 c.cm. The following is the method used for making up the required amount of complement plus saline in 0·5 c.cm. volume to each tube. This may be best given by an example. Let us presume that there are 44 sera to be tested and the M.H.D. of 1/15 complement is 0·14 while the amount of complement fixed by 0·3 c.cm. of antigen in 0·06. For practical purposes we should allow for 50 sera to be tested and provide for an excess of complement. In this example 3 c.cm. would be in excess.

After the complement has been added, pipette a further 0·3 c.cm. of saline into each of the two control tubes and 0·3 c.cm. of antigen into the four tubes of the test proper. Each tube then contains a volume of 1 c.cm. All the tubes are shaken and allowed to stand for one hour at room temperature and are then placed in the water-bath at 37° C. for another hour, at the end of which time, and while the racks are still remaining in the water-bath, 1 c.cm. of sensitised cells is added to each tube. The tubes are shaken and at the end of half an hour the racks of tubes are taken from the water-bath and allowed to stand at room temperature for 15 minutes, when the results are read.

TABLE III.

First Control Tube to Contain 1½ M.H.D. Complement.

1/15 comp. .. 0·21 c.cm. × 50 = 10·5 c.cm.
Saline .. .. 0·29 c.cm. × 50 = 14·5 c.cm.
25·0 c.cm.

Mix in Jar 1 and pipette 0·5 c.cm. into all first control tubes.

Second Control Tube and First Tube of Test Proper to Contain 1½ M.H.D. plus Amount of Complement Fixed by Antigen.

1/15 comp. .. 0·21 c.cm. + 0·06 c.cm.
= 0·27 c.cm. × 100 = 27·0 c.cm.
Saline .. .. 0·23 c.cm. × 100 = 23·0 c.cm.
50·0 c.cm.

Mix in Jar 2 and pipette 0·5 c.cm. into all second control tubes and first tubes of test proper.

Second Tube of Test Proper to Contain 2 M.H.D. plus Amount of Complement Fixed by Antigen.

1/15 comp. .. 0·28 c.cm. + 0·06 c.cm.
= 0·34 c.cm. × 50 = 17·0 c.cm.
Saline .. .. 0·16 c.cm. × 50 = 8·0 c.cm.
25·0 c.cm.

Mix in Jar 3 and pipette 0·5 c.cm. into all second tubes of test proper.

Third Tube of Test Proper to Contain 2½ M.H.D. plus Amount of Complement Fixed by Antigen.

1/15 comp. .. 0·35 c.cm. + 0·06 c.cm.
= 0·41 c.cm. × 50 = 20·5 c.cm.
Saline .. .. 0·09 c.cm. × 50 = 4·5 c.cm.
25·0 c.cm.

Mix in Jar 4 and pipette 0·5 c.cm. into all third tubes of test proper.

Fourth Tube of Test Proper to Contain 3 M.H.D. plus Amount of Complement Fixed by Antigen.

1/15 comp. .. 0·42 c.cm. + 0·06 c.cm.
= 0·48 c.cm. × 50 = 24·0 c.cm.
Saline .. .. 0·02 c.cm. × 50 = 1·0 c.cm.
25·0 c.cm.

Mix in Jar 5 and pipette 0·5 c.cm. into all fourth tubes of test proper.

In the very rare instances when the M.H.D. of complement without antigen is above 0·14 the amount of saline dilution of the M.H.D. or M.H.D. of complement plus that fixed by the antigen is made in a volume of 0·75 c.cm., since this is not possible in 0·5 c.cm. exemplified above, and the final total amount in all tubes, including controls, becomes 2·25 c.cm.

The hæmolytic systems with and without antigen and a negative and positive serum are put up as controls at the time of each test. As the amount of complement fixed is found not to be related to the clinical state or to prognosis in the disease, further tubes appear unnecessary, and on practical lines are advantageously omitted. It may be recalled that serum plus antigen cannot be taken to fix the amount of complement fixed by each separately.

To give a general working rule we consider when tubes 1 and 2 of the control are completely hæmolysed or tube 1 completely or almost hæmolysed and tube 2 completely hæmolysed, then—

Fixation in tubes 1, 2, 3, and 4 of the test denotes a strong positive result.

Fixation in tubes 1, 2, and 3 of the test denotes a positive result.

Strong fixation in tubes 1 and fixation in tube 2 only denotes a weak positive result.

Weak fixation in tubes 1 and 2 only denotes a border-line result.

Fixation in tube 1 only denotes a negative result.

We beg to thank the Director-General Medical Services, Ministry of Pensions, for permission to publish this paper, and we wish to note the loyal assistance of our staffs, especially that of Mr. T. Harrison and Mr. Thompson in the carrying out of this work. During the course of our work we have done the T.C.-F.R. on 15 cases of renal tuberculosis, and in all the reaction was positive. The reaction carried out upon 30 surgical cases in hospital and showing no signs or symptoms of tuberculosis gave a negative result in all.

INCENDIARISM IN ADULT MALES;

WITH SPECIAL REFERENCE TO THE SUBNORMAL AND MENTALLY DEFECTIVE PERSON.*

By H. T. P. YOUNG, M.B., Ch.B. Edin.,
MEDICAL OFFICER AT H.M. CONVICT PRISON, PARKHURST.

Among offenders who undergo a routine mental examination before trial at remand prisons are those charged with arson, and the cases now under consideration were received at Brixton Prison during 1921, 1922, and 1923, at that time in the medical charge of Dr. W. Norwood East, to whom I am greatly indebted for advice and criticism.

Frequency and Incidence of Arson.

The total number of prisoners detained there during this period was 23,959, of whom 36 were accused of arson, representing a percentage of 0·15. The number of convictions for this offence throughout England and Wales at the same time amounted to 170, being 0·83 per cent. of all persons convicted on indictment. It should be pointed out that the total number of admissions to Brixton includes persons accused of indictable as well as non-indictable offences.

From 1900 to 1923, excluding war years, the average number of males convicted for arson amounted to 71 per annum, females representing only 4·6 per annum.[1] Fluctuation in this number has occurred from year to year, but, although alcoholic excess, which is reputed to have a marked effect on the incidence of the crime, was noted in many of the persons examined in the present series, it was found that the diminution in the number of cases of arson has not been commensurate with the very great reduction in the consumption of alcohol dating from 1900.[2] The act of arson renders the offender liable to the severest penalties. In one extremely rare class of case arson is punishable with death under statutes which are still unrepealed—viz., when it consists in setting fire to a king's ship or dockyard, or to any ship in the Port of London (Outlines of Criminal Law —Kenny). Penal servitude for life can be given in less serious cases, while shorter terms of penal servitude may be inflicted for attempts or threats. Although a sentence of penal servitude is given with comparative frequency in these cases, the length of the sentences, in common with those for other offences, has been considerably reduced in recent years. The incendiary, however, is a person for whom the public has little sympathy, and popular opinion as to his blameworthiness has shown perhaps less change than it has towards other offenders.

Incendiarism occurs at all ages, but in the present series it was found to be more common in the second, third, and fourth decades.

Motives for the Crime.

The motives of fire-raisers generally fall under one of the following heads: (1) Defrauding insurance companies either directly or indirectly; (2) hiding evidence of guilt—e.g., in cases of theft; (3) avoiding conviction and sentence to a military prison; (4) to obtain shelter in prison on account of unemployment or destitution; (5) revenge, hatred, anger, or fear; (6) mischief; (7) nostalgia.

In order to show in what respects fire-raising differed from other forms of wilful destruction of property, the cases were contrasted with a number of histories of persons charged with committing malicious damage. The most obvious difference was found to be that arson rarely followed the alleged cause with such rapidity as did malicious damage. In the majority of arson cases it is possible to elicit a plan of some sort, and, in consequence, it would be rare for arson to arise from a chance impulse which is not resisted, whereas in malicious damage this is not uncommon. The crime necessitates some preparation, however crude it may be. That recurrent impulses occur to set fire to property is not disputed, but in none of the cases examined could the action be described as impulsive, in the generally accepted meaning of the term, and a comprehensible reason for it could usually be obtained. Malicious damage occurs with greater frequency than arson, at any rate in urban districts.

Incendiarism and Mental Defect or Disease.

A series of 40 cases, taken from notes of persons remanded for mental examination after a charge of malicious damage, was examined, and it was found that 10 per cent. were mentally defective, 60 per cent. were insane, and 30 per cent. were normal. In the arson cases mental disease in some degree was frequently found to be present, 11 of the 36 Brixton cases being so affected, amounting to about 30 per cent. of the whole, while 9 were subnormal or certifiable as mentally deficient, representing 25 per cent. In a supplementary group of 8 cases, which were not included in the Brixton figures, 3 were regarded as insane and 3 as subnormal or defective.

In Baker's figures,[3] drawn from the admissions to Broadmoor between 1864 and 1886, where they had been sent, after conviction for arson, as criminal lunatics, about 35 per cent. were found to be congenital imbeciles, the remaining 65 per cent. being insane. It should be noted that arson arising in cases of mental disease or defect is more often a rural offence, and that the majority of admissions to Brixton are drawn from the London area. Mental inefficients form about 5 per cent. of the remand prison population, and it has been shown that 2½ per cent. of certifiable defectives are charged with arson.[4]

Sullivan observes[5] that 52·9 in every 100 persons convicted for stack-firing are defective, while in cases of arson of all kinds 16·7 per cent. only are so affected. The inclusion of subnormal persons, who cannot be dealt with under the Mental Deficiency Act, would doubtless increase these percentages. The number examined in the present series was, however, too small to justify the quoting of figures, but it was noted that while the insane offender more often set fire to buildings, the subnormal or defective was responsible for the majority of stack fires.

The preponderance of defectives over others in cases of stack-firing is, on the whole, characteristic of their level of intelligence. Their inability to achieve success in any but the simplest manner and their liability to suffer from feelings of inferiority help to determine their choice of expression. Arson, in common with other offences, may become habitual in these cases, Nos. 1 and 3 in the appended histories serving as illustrations of this fact. As a rule defectives show little or no regret for the loss to others of which they are the cause. Revenge is their most common motive, but they are often indifferent upon whom the loss falls. Their impulses would appear to undergo little if any modification until they reach perceptual levels, and the consequent limitation of their field of action would account for these features in their conduct. None of the defectives seen were below the feeble-minded class, the lowest mental age being about 7½ years.

The case of the moral imbecile differs from other types of defectives. Recorded cases indicate that whenever incendiarism has occurred among their delinquencies, and it is not at all infrequent, the crime has been committed with superfluous thoroughness. Whereas the feeble-minded person may be able to form some estimate of the criticism of his conduct by others, the moral imbecile is incapable of doing so. He is insensible to opinion as to the purposelessness of his offence or to its effect on his own welfare. His crime lacks adequate inducement. He is careless of incriminating himself, whereas the feeble-minded person may make such endeavours, as are within his power, to hide the evidence of his guilt. Unlike the latter, the moral imbecile shows no preference for any particular form of delinquency, characteristics of his criminal activities being their variety and the absence of any stereotyped habit.

---

* This paper is published with the consent of the Directors of Convict Prisons, but does not necessarily represent their opinions.

A morbid impulse to burn is not limited to any particular group of psychoses or to mental deficiency, and, for this reason, it seems probable that the impulse is of accidental origin. The presence of an alleged irresistible impulse to commit an incendiary act, unless accompanied by definite signs of mental disease or defect, cannot be held to relieve an accused person of his responsibility. The condition, moreover, is not recognised in English criminal courts.

The mental states of the offenders examined in the present series were as follows:—

Mental deficiency	5
Subnormal	7
Mental instability	4
Manic depressive	2
Chronic delusional insanity	1
General paralysis	1
Dementia præcox	2
Paranoid dementia	1
Dementia	1
Mental enfeeblement	2
Normal	18
Total	44

Illustrative Cases.

Subnormal and Mentally Defective Persons.

1. Subnormal; criminal intent; criminal habit; recurrent impulses to burn; inferiority complex.

T. H., aged 45, general labourer, convicted for setting fire to a haystack after four convictions for arson and 14 for malicious damage.

Family History.—A maternal aunt was in an asylum and his maternal grandfather was paralysed. A sister suffered from hysterical fits. There was no history of epilepsy or intemperance.

Personal History.—The prisoner was the second child in a family of five; when 6 months of age his house caught fire, but none of the family sustained any injury. He left school in Standard VI. and was in fairly regular employment as errand boy until 19 years old, since when he has worked intermittently as a general labourer. During the war he served for three years in Egypt, being employed chiefly in the cook-house, and after demobilisation in 1920 he did odd work until 15 months before the present offence. He was a teetotaller and he denied syphilis. He was unmarried. In 1921 he had an attack of acute rheumatism. There was no history of fits and he had never been in an asylum. As a boy he did not get on well at home and when, at the age of 19, he ran away he was told that he need not return. He was frequently in trouble for playing with fire. Soon after he ran away he became destitute, and he then began his career of incendiarism and wilful damage which has continued with short intervals up to the present time. He admitted that he broke windows in order to get into prison.

For 15 months before the present offence the prisoner lived on unemployment pay. He alleged that a fortnight before the arson he began to feel depressed and restless. He attributed this to being out of work. He stated that he then felt, as before, a desire to set light to a rick. Arson of buildings did not attract him as a house did not blaze so well! He was not in debt or in trouble of any kind. He walked out into the country and while crossing some fields he threw away his match-box in order to overcome his desire to burn, but he subsequently returned and found it. He then set fire to the rick and waited until he was arrested. He did not know the owner of the property. He admitted to a feeling of relief after he had committed the offence.

His previous convictions were all of the same character. On several occasions he had given himself up to the police and pleaded guilty at the trial. He described the present offence frankly and he added that in similar circumstances he would repeat it, well knowing the nature and quality of the act and that it was wrong. The prisoner asserted that when at work he was not subject to attacks of depression with the accompanying desire to do an incendiary act, and that he was contented in prison, where he was given very simple work, because the employment was regular. His general knowledge was poor. With intelligence tests he reached the level of 14 years. He was suggestible and of a low type physically and mentally, but he was even-tempered, well conducted, and persistent in application while in prison. A mitral bruit and signs of old pleurisy were found.

2. Feeble-minded; malingering loss of memory; indifference as to the effect of the crime on others; revenge.

J. E. S., aged 30, labourer; charged with setting fire to five ricks, and suspected of rick-firing in the same neighbourhood for two years before arrest. The family history was negative.

Personal History.—The prisoner left school in Standard I. and worked as a hay-binder until joining the army in 1914. He stated that while in France he had an injury to his head, but that he was not in hospital or otherwise treated for it. On leaving the army he got work on a hand pump at 5*s.* a week. At the police station he admitted setting fire to the ricks, using oily rags, adding that he went mad at times and was not responsible for his actions. When examined he alleged that on one occasion he lost his memory for three days, and that at another time he found himself 13 miles from home without knowing how he got there. He recollected going to the rickyard on the present occasion and that he was smoking a pipe. He stated that he then fell down and dropped the pipe. When he came to himself 10 minutes later he found the ricks burning. The accused then went home. He added that one rick belonged to his father's employer, another was the property of his own master, and he could not remember about the remainder. He denied, however, that he had any grudge against the owners, but he complained that ex-Service men had not been fairly treated as work was not found for them.

He had no previous convictions, there was no history of intemperance, and he had never been in an asylum. He could not read or write. His mental age was about 7½ years. His general knowledge was poor—he could not tell the time, and he was unable to give change or do simple arithmetical sums. There was no scar on the head. His physical condition was good, but the Wassermann test was doubtful.

In view of the conflicting accounts which he gave of the offence, the unconvincing description of the alleged attacks of loss of memory, and the fact that the rick-firing took place at several spots in the neighbourhood, and probably over a considerable period of time, the loss of memory was not regarded as genuine.

3. Subnormal; feeling of inferiority.

G. S., aged 37, labourer; charged with setting fire to two wheat stacks. There was nothing of note in the family history.

Personal History.—The prisoner was the illegitimate child of a domestic servant. He was brought up from the age of 3 months by a foster-mother. He left school in Standard V. and afterwards worked as a farm labourer. In 1908 he was sentenced to three years' penal servitude for setting fire to a rick, the offence, he stated, taking place while he was drunk. Five months after discharge he repeated the offence. He was out of work at the time and had been drinking. He was sentenced to four years' penal servitude. He served in the army for two years, and during that time he was thrice convicted for theft. Four months after leaving the army he was sentenced to four years' penal servitude for stealing money, and four months after the completion of his sentence he committed the present offence. During the interval between his discharge and re-arrest he was out of work and living with his sister. There was no history of syphilis, epilepsy, or insanity. He was unmarried. Although a heavy drinker, he denied that he was under the influence of drink at the time of the offence.

The crime with which he was charged took place during a journey into the country. At 3.30 A.M. he made his way across some fields and set light to the stacks, after which he walked several miles in order to give himself up to the police. He stated that he committed the offence in order to get into prison, where he was more contented than when outside, because he there associated with his equals. In prison he was quiet and well behaved. His general knowledge was fair and he had a mental age of about 10 years.

General Paralysis.

J. S., aged 50; charged with setting fire to a haystack. The family history was negative. This man was in regular employment at a high rate of wages until a year or so before the date of the offence. Employment then became more difficult to obtain, and the accused's earning capacity gradually declined. For several months before his arrest he had no work. He had never been in prison before. There was no history of fits or insanity. He denied having had syphilis. He was married and had three children, the youngest one being 10 weeks old. He denied sexual excesses. There was a history of recent whisky drinking. He had been suffering from pains in the head for two months before the offence. His account of the crime was confused, but it appeared that after watching a football match in a field near his house he threw a lighted match into some dry grass, and although he admitted that he saw the fire spread to the rick, he went home without troubling to put it out. He was arrested five minutes later. The prisoner had delusions of exaltation concerning his vocal powers. While under observation he was found to commit petty thefts in the ward, and he was seen to put urine in his food on two occasions. The Wassermann test was positive. Argyll Robertson pupils, exaggeration of the knee-jerks, and other confirmatory signs were present.

The act is an illustration of the utter disregard for consequences to himself or to others which is commonly seen in the delinquencies of general paralytics.

Paranoid Dementia.

S. R., aged 27, no occupation ; charged with setting fire to an occupied dwelling-house and with attempting suicide by hanging. When arrested the accused said : " I did it to do the woman downstairs a turn. I then tried to hang myself, but the rope broke." There was no family history of alcoholism, epilepsy, or insanity.

The prisoner left school in Standard V. and remained at work until he joined the Army. In 1919 he returned home and, as his mother was dead and he could get no work, he looked after the house for his father and sister. When the dole was discontinued he became depressed and tried to drown himself in the river. Later on he became much upset as he thought that people were trying to turn him and his father out of their rooms because he heard them saying : " We can't get the rooms." He was also annoyed because the landlady instructed a builder to do some small repairs when he thought that she ought to have given the work to him. This was the cause of his spite against her. He also believed that she tried to poison him and that people wanted to turn him out because they thought he had immoral relations with his sister.

For two nights before the crime he had no sleep. While alone in the house he made two attempts to hang himself and another to poison himself with gas. He then scratched his neck with a razor. Finally he put candles in various parts of the room and set light to some heaps of paper and clothing on the floor. While under observation he complained that other prisoners were making signs referring to his sexual habits.

Dementia Præcox.

J. Z., aged 21 ; charged with arson of a haystack. The accused was born in England of alien parents who returned to live in their own country several years before the war. When 12 years of age he and his father were interned until 1918. On his release he returned home and spent his days sitting about and brooding. On account of his depression he was sent to North Africa for two years, but his health did not improve. He then went as shop assistant to his uncle in England, but after a few weeks he suddenly left the house with a small sum of his own money and wandered about the North of England for three months without informing his relatives of his whereabouts. Eventually he was found on the road in an exhausted state and was taken into hospital. He could give no reason for his behaviour. Although he was on very friendly terms with his uncle he again left the house a few days after his return and made his way to a suburb where the arson took place. The police found him sitting by the burning rick going through the motion of striking matches. When examined he admitted that he set fire to the rick because he had done something for which he thought he should be punished. In this he referred to masturbation. He was very depressed and he gave a history of having attempted suicide on four occasions since the age of 11. He denied having had any homosexual experiences either at the internment camp or since that time.

Chronic Delusional Insanity.

D. A. B., aged 46, shoemaker ; charged with setting fire to an occupied dwelling-house. The accused came to England from the Continent in 1899 and for many years he was employed as an expert shoemaker. Nothing abnormal in his conduct was observed until after his return from serving in his country's army in 1919, when his wife noticed a change in him. Ten months before the arson his favourite daughter died, and about the same time he had an attack of influenza. As a result he became depressed and was unable to work. His wife stated that he barricaded his room and would allow no one to enter it except herself and her son, and the accused remained shut up for about a year. An attempt to certify him as insane was frustrated by the prisoner's refusal to open the door.

While living in this way he constructed a sort of cage from the framework of an iron washstand, some sacking, and rope, and he attached this by a stout wire to the foot of his bed. At the time of the fire he was seen standing up in the cage, which was hanging out of the window at the end of the wire. When examined he gave no adequate reason for the offence, but he said that in 1900, while working with a number of compatriots, a lady came to the shop and the accused believed that she conceived an infatuation for him because he had a " Church " name. He tried to get employment in her house, but, owing to jealousy, he was prevented from doing so. There was never any communication between him and the lady, but prisoner came to the conclusion that she was of royal birth. On account of the jealousy he believed that he and his family were marked out for destruction, and as a protection he shut himself up in his room and constructed the cage as a means of escape. There was no history of alcoholism or syphilis. At the trial the prisoner was found insane on arraignment.

ON PYRIDINE-β-CARBONIC ACID DIETHYLAMIDE

AND ITS USE AS AN ANALEPTIC.

By EDWIN STANTON FAUST, A.B., PH.D., M.D.

THE older schools of medical practitioners knew and appreciated the clinical value of quite a number of drugs or therapeutic reagents collectively termed " analeptics." Modern pharmacology (perhaps as a result of exaggerated nihilistic tendencies in therapeutics) seems to be losing sight of this class of drugs, and the term analeptic seems to be disappearing from scientific medical literature. In the last edition of Cushny's " Text-book of Pharmacology and Therapeutics " (1924), for example, the time-honoured term analeptic does not even appear.

Analeptics.

Analeptics may be defined as pharmacological reagents, acting (directly or indirectly) primarily, and some of them apparently electively, upon certain regions or sections of the central nervous system and certain peripheral organs, so that their functions are stimulated. Modern pharmacology, it is true, has dispensed with many of these substances, and only a few remain in present-day pharmacopœias. Among these are to be mentioned certain purin derivatives (caffeine, theobromine), strychnine, and camphor. One might add that adrenalin and pituitary extracts, under certain conditions, might well be enumerated under this head, and still others could be named ; atropine, for instance, so far as the respiratory centre is concerned. It is needless to mention the many disadvantages of atropine in view of its many concomitant actions. For practical purposes the first-mentioned substances—i.e., camphor, caffeine, and strychnine—are certainly the best known and most frequently used analeptics.

On comparing the relative and absolute practical value of these substances it becomes clear that no one fulfils the needs of the medical practitioner. Strychnine, as is well known, affects mainly the spinal cord, and to a much lesser degree the higher nervous centres. Again, the cumulative action of strychnine is liable to give rise to certain difficulties and inconveniences when, as is generally the case, its absorption is not paralleled by its excretion. Regarding the inefficiency of strychnine in pathological conditions of the circulatory apparatus, the reader is referred to Cushny (loc. cit., p. 285).

Camphor has quite as many if not more disadvantages than strychnine. First, it is practically insoluble in water, and the administration of oily or ethereal solutions has numerous inconveniences and disadvantages. Among these are such local effects and lesions as subcutaneous pseudo-tumours, as Nicod[1] has recently shown. But, besides, camphor very quickly undergoes chemical changes in the animal body, and the products thus formed by oxidation and union with sulphates or glycuronic acid are pharmacologically inert. The rapid decomposition of camphor after injection results in marked tolerance, so that frequently renewed injections become necessary. And finally, be it remarked, that accepting Cushny's version and views on the subject, the therapeutical value of camphor as a heart stimulant seems altogether questionable. Cushny says :

> " The value of camphor in heart diseases is still far from being established. Solutions of camphor in oil have been

injected subcutaneously in these cases, but they cause pain and swelling at the point of injection and are valueless."

The methods of administering camphor, proposed by Leo and by Fischer, by intravenous injection in very dilute aqueous solution or oily solution, have not stood the practical test. Certainly these methods have not yet attained universal acceptance, and the risks incurred in their use are certainly not a *quantité négligeable.*

The disadvantages of the purin derivatives as analeptics are sufficiently well known, so that we need not enter upon a discussion of their pharmacological demerits here.

It therefore follows from the above considerations that every new addition to the number of available analeptics in the sense above defined must be reckoned a decided gain in therapeutics. It is for this reason that we have in the course of the last few years studied a number of organic compounds whose chemical constitution promised to further the materialisation of our wishes. We have investigated a large number of derivatives of camphor and have found that among the derivatives of camphoric acid there are such compounds to be found, whose pharmacological actions approximate very closely to those of camphor itself—e.g., camphoric acid diethylamino-ethyl-imide. At the same time our researches have led to the discovery that certain carboxylated pyridine derivatives, in spite of the absence of ring-substituting aliphatic radicles as are found in the case of the camphor molecule, do nevertheless show in animal experiments many actions closely allied to those produced by camphor itself. Among the bodies of this particular group we have found that pyridine-β-carbonic acid diethylamide has, in man and other warm-blooded animals, the desired camphor-like actions in the most pronounced degree. Before entering upon a discussion of the pharmacology of this substance, we will mention its principal physical and chemical properties.

Pyridine-β-Carbonic Acid Diethylamide.

Pyridine-β-carbonic acid diethylamide is a viscous, faintly coloured, almost inodorous liquid, which distils over at a temperature of 150° C. at a pressure of 2 mm. Hg. It is easily soluble in water in every proportion, also soluble in the usual organic solvents. The aqueous solution is tasteless.

Pharmacological Data.—1. *Action on Normal Animals.*—After injection of an aqueous solution (1 c.cm.) of 0·1 g. pyridine-β-carbonic acid diethylamide into an ear vein of a rabbit, one notes that the animal shows almost immediately decided signs of its stimulating effects. Most apparent and striking is the *increase in the respiratory rate.* The animal, previous to the injection quiet and dull and indifferent to its surroundings, soon appears excited, jumps and leaps about, rises up on his hind feet, and appears abnormally interested in its environment. At the same time it appears timorous. On touching the animal with a stick it is liable to become aggressive. Touching its nose or whiskers results in efforts at self-defence, unwarranted by and out of all proportion to the intensity of the mechanical insult offered. At the same time one notes decided signs of increased reflex irritability. In male animals the sexual instincts and functions seem abnormally stimulated and augmented. After a lapse of from 15 to 20 minutes the action reaches its climax ; thereupon respiration slows down and becomes again approximately normal ; the tremor previously noted disappears, and the general excitement abates.

If the doses injected are increased, then after 10 or 15 minutes convulsions come on. In the initial stage these appear first in the form of twitchings in the muscles of the jaws and facial muscles (trismus). At the same time, or very soon after, there is a marked bending backwards of the head (opisthotonos). Finally, general convulsions supervene and these clonic-tonic convulsions are very similar to those produced by camphor. Sometimes there are remissions, whereupon the convulsions may again set in. In such cases the animal may succumb in consequence of respiratory standstill. If the animal survives, there may follow another attack of convulsions, weaker than the last, and then recovery usually ensues.

In dogs similar phenomena are observed. Here also is noted an increase of respiratory rate and in some cases, as with rabbits, signs of decided cerebral excitement. As regards increase of reflex irritability and convulsant action, dogs appear more sensitive than rabbits.

In guinea-pigs, mice, and rats the action is qualitatively the same as in rabbits. We would call special attention to the fact that in frogs pyridine-β-carbonic acid diethylamide acts as a paralysant and herein shows a further pharmacological analogy with camphor.

Subcutaneous injections of pyridine-β-carbonic acid diethylamide result in exactly the same phenomena, which, however, naturally set in somewhat later.

We desire to emphasise that *stomachic introduction* of this substance readily and quickly causes exactly the same symptoms. This fact is of practical therapeutical interest and importance, inasmuch as it shows that resorption of pyridine-β-carbonic acid diethylamide from the intestinal tract is accomplished quickly ; and that therefore this substance can be given for therapeutical purposes per os with exactly the same effects as when injected intravenously or hypodermically.

2. *Action of Pyridine-β-Carbonic Acid Diethylamide on Blood Pressure.*—Rabbit, body-weight 2·3 kg., curarised ; artificial respiration. Average blood pressure before giving, 98 mm. Hg. Intravenous injection of 20 mg. pyridine-β-carbonic acid diethylamide caused rise of blood pressure from 98 to 130 mm. Hg.

3. *Blood Pressure and Respiration.*—Rabbit, urethane hypnosis. Initial blood pressure 85, rose to 120 mm. Hg after three injections of $\frac{1}{6}$ gr., $\frac{1}{3}$ gr., and $\frac{1}{6}$ gr. each. Respiration before injection of pyridine-β-carbonic acid diethylamide, 30 per minute, after five minutes, 46 per minute.

In another experiment the blood pressure rose from 80 to 120 mm. Hg, and respiration increased from 40 to 58 per minute after two injections of $\frac{1}{3}$ gr. and 3 gr. each. (Compare Fig. 1.)

4. *Action on the Frog's Heart.*—Pyridine-β-carbonic acid diethylamide causes *slowing of the pulse-rate* and *increase of pulse-volume.* It diminishes and finally overcomes the depressant action of alcohol, chloral hydrate and chloroform on the heart. (Compare Fig. 2.)

There is no digitalis-like action. The new drug is, however, compatible with injectible digitalis preparations and may therefore be injected simultaneously and in the same syringe with these, if thought desirable. I have been informed that remarkable results have been obtained by substituting pyridine-β-carbonic acid diethylamide for digitalis in the later stages of digitalis treatment. Atropine does not alter the character of the action of pyridine-β-carbonic acid diethylamide on the heart.

It is evident that the above action of pyridine-β-carbonic acid diethylamide on the heart must result in better filling of the arterial system.

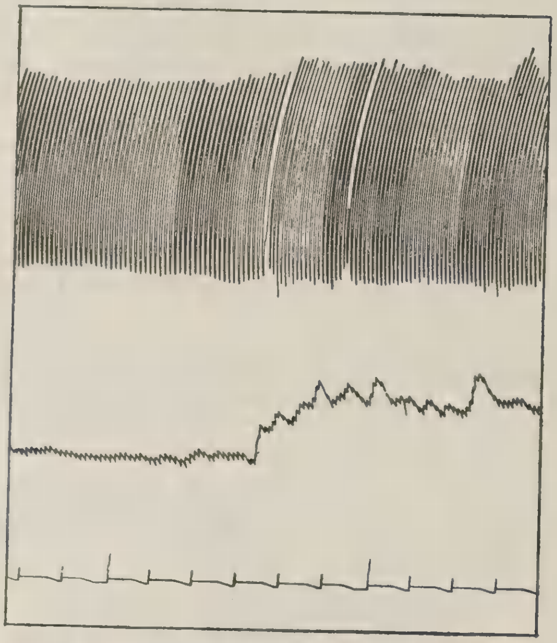
5. *Action of Pyridine-β-Carbonic Acid Diethylamide on the Respiratory Volume.* — I have been able to show by animal experiments that not only is the respiratory rate increased by pyridine-β-carbonic acid diethylamide, but that at the same time the respiratory volume is also increased. Illustrative of numerous experiments conducted on rabbits may be quoted the following :—

After injection of 50 mg. pyridine-β-carbonic acid diethylamide the respiratory volume rose from 350 to 440 c.cm. ; and again, after further 50 mg. pyridine-β-carbonic acid diethylamide, to 490 c.cm. Thereupon the respiratory volume was reduced to 290 c.cm. by intravenous injection of 50 mg. morphine. Injection of 50 mg. pyridine-β-carbonic acid diethylamide raised the respiratory volume from 100 c.cm. (morphine action) to 300 c.cm.—i.e., approximately the normal respiratory volume (Fig. 3).

6. *Action on Blood-Vessels.*—(*a*) Using a Krawkow preparation of the isolated rabbit ear, it can easily be demonstrated that small doses of pyridine-β-carbonic acid diethylamide—for example, ½ c.cm. of a solution 1 : 1000 or ½ c.cm. of a solution 1 : 100 *contract the blood-vessels,* whereas larger doses—½ c.cm. of a solution 1 : 10—cause vaso-dilatation. (*b*) The same phenomena may be observed after intravenous injection of pyridine-β-carbonic acid diethylamide in a rabbit whose blood pressure was previously lowered to 40–70 mm. Hg by means of chloral hydrate. The blood pressure rises rapidly to 80 mm. and mounts steadily to almost normal pressure—i.e., approximately 95 to 100 mm. Hg.

7. *Action on Smooth Muscle.*—In this connexion it is of interest and important to note that smooth muscle is stimulated by pyridine-β-carbonic acid diethylamide as demonstrated in the following experiment : Rabbit gut in Tyraude bath of 100 c.cm. Addition of 1 c.cm. pyridine-β-carbonic acid diethylamide solution 1 : 100 results in increased tonus and increased peristalic movements (Fig. 4).

FIG. 1.



Rabbit, body-weight 2·3 kg. Urethane hypnosis, intravenous injection of 0·05 g. pyridine-β-carbonic acid diethylamide.

Blood pressure ..	60 mm. Hg	66	—	100	—
Respiration (rate)..	66	60	72	73	72

Summary of Pharmacological Results.

From the above it is evident that—

1. Pyridine-β-carbonic acid diethylamide, being soluble in water in every proportion, is quickly resorbed from the stomach as well as after subcutaneous injection, and that its resorption results in camphor- and caffeine-like pharmacological actions.

2. Pyridine-β-carbonic acid diethylamide causes stimulation and increase of the functions of automatic centres in the medulla oblongata (vasomotor and respiratory centres), and at the same time direct stimulation of the heart, resulting in—

3. *Rise of blood pressure* and *increase of respiratory movements;* at the same time *respiration volume is also increased.*

4. It is therefore evident that in all such cases, in which these functions have fallen below normal, as, for instance, in the case of collapse from any cause whatever, pyridine-β-carbonic acid diethylamide is, as a result and in consequence of its stimulating properties, able to combat, correct, or overcome such pathological conditions.

5. As compared with strychnine, it has the great advantage that its main action is exerted principally on the automatic centres in the medulla, while strychnine acts mainly on the spinal cord. Another advantage over strychnine is the fact that pyridine-β-carbonic acid diethylamide is *devoid of cumulative action.*

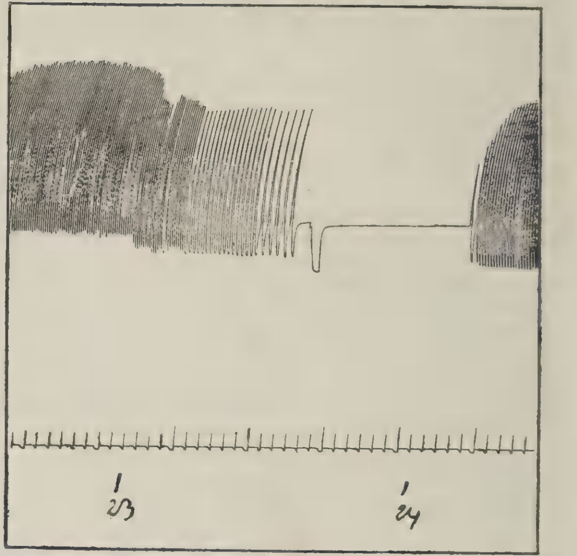
6. Note also the peripheral action on smooth muscle, resulting in vasoconstriction and thus causing further rise in blood pressure.

Pyridine-β-carbonic acid diethylamide shows a wide therapeutic range, that is to say, the *effective therapeutic dose* is far below the toxic dose, and the toxic dose is again far below the lethal dose. To quote figures, the following example :—

Effective intravenous dose for rabbits	0·005 g. to 0·01 g.
Toxic dose for rabbits	0·10 g. to 0·12 g.
Lethal dose for rabbits	0·20 g. to 0·30 g.

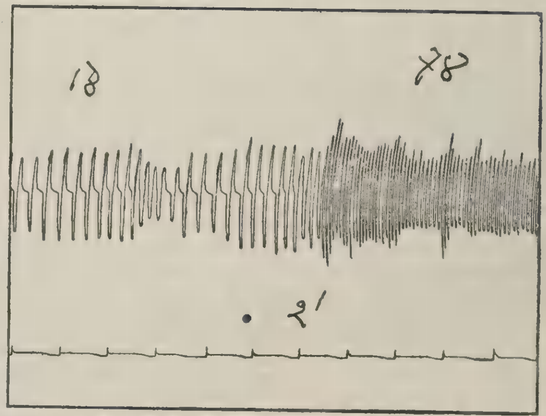
I therefore hold that pyridine-β-carbonic acid diethylamide bids fair to prove a valuable substitute not only for strychnine, but also for camphor and caffeine, inasmuch as its stimulating action is exerted

FIG. 2.



Frog's heart on Straub cannula, holding about 1 c.cm. At 23 normal; thereupon 1 c.cm. chloral-hydrate solution 1 : 5000. Heart stops at 24. 1 c.cm. pyridine-β-carbonic acid diethylamide 1 : 5000. The heart begins to beat again at once and soon attains normal pulse-rate and pulse-volume.

FIG. 3.



Rabbit, body-weight 2·85 kg. Intravenous injection of 0·01 g. morphine-HCl. Respiration-rate drops to 18; at 2 intravenous injection 0·05 g. pyridine-β-carbonic acid diethylamide. Respiration-rate rises from 25–35 to 78.

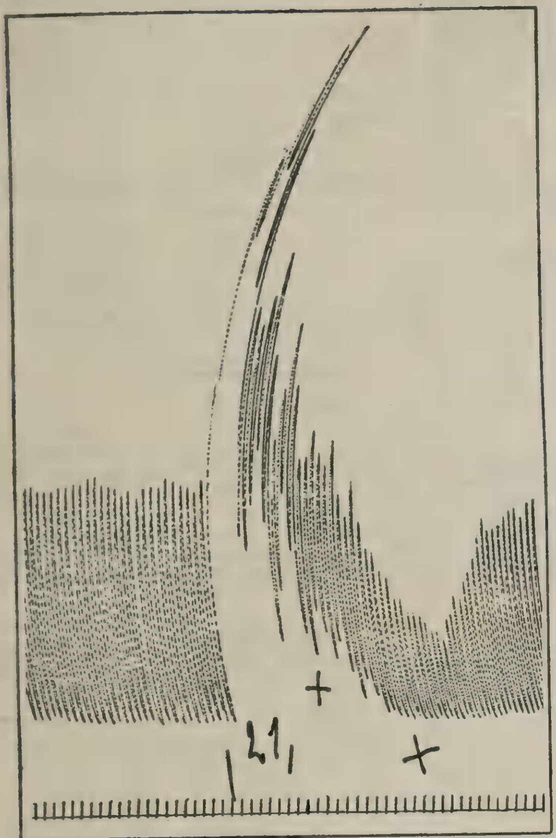
equally and simultaneously on the central nervous system and on the circulatory and respiratory apparatus. It is also evident that a substance endowed with pharmacological properties, as above described, should prove a valuable "tonic" in the general sense of the word.

Records of Clinical Use of the Remedy.

Pyridine-β-carbonic acid diethylamide (designated P.) has been used with success in the cases here given:—

CASE 1.—Woman, aged 50. Emphysema. Dilatation of right heart with arrhythmia and extreme cyanosis. P. was given intravenously, beginning with 0·5 c.cm. and increasing up to 2 c.cm. Result: Rapid improvement of symptoms of cardiac insufficiency—cyanosis and dyspnœa. Was able to sleep at night. On discontinuing the treatment cyanosis and dyspnœa returned. Immediate improvement on further injections of P. No marked effect on blood pressure noted. The patient had 2 c.cm. P. twice daily for a fortnight without untoward symptoms, and improved so far as to be able to leave her bed and to show no further symptoms of cardiac insufficiency. While P. was used no other heart stimulant or tonic was given.

FIG. 4.



Rabbit gut; Tyraude bath 100 c.cm. Addition of 0·01 g. pyridine-β-carbonic acid diethylamide causes increase of peristaltic movements and tonus.

CASE 2.—Patient, aged 25. Heart failure (muscular insufficiency) with venous engorgement. P., 1 c.cm. twice daily, was given for a week. Marked improvement. Blood pressure unaltered. Patient requested continuance of treatment.

CASE 3.—Patient, aged 60. Cardiac insufficiency (muscular). Passive bronchitis. P. given, 2 c.cm. twice daily for several days. Marked improvement, subjective and objective after each injection, but good results were transient and patient died.

CASE 4.—Patient, aged 67. Cardiac insufficiency, the result of granular contracted kidney. Œdema very pronounced. Pulse-rate 120. Blood pressure (Riva Rocci) 180–110. Patient reacts well to digitalis, after which pulse-rate is reduced to 60. Blood pressure rises to 200/110. Sudden rise of temperature; hæmorrhagic lung infarct. Digitalis discontinued and P. given instead, intravenously, 1 c.cm. twice daily. Patient stands this change of treatment very well. No increase in pulse-rate, which remains at 70–80, while pulse full and strong. Later on digitalis given again with good results.

CASE 5.—Patient, aged 33. Broncho-pneumonia, measles. High temperatures during a fortnight. Bilateral pulmonary foci. Patient receives 1–2 c.cm. P. intravenously *pro die*, and does exceedingly well under this treatment. Blood pressure remains at 115–120. No signs or indications of heart failure whatever.

CASE 6.—Patient, aged 53. Coronary sclerosis, arteriosclerotic affection of the myocardium. Severe dyspnœa even after only slight exertion. Feeling of oppression in the præcordia; of weight and constriction of chest. No œdema; no irregularity of the pulse. Pulse-rate between 80 and 90. Patient is given 1 c.cm. P. daily for a fortnight, with much apparent benefit. Result: Dyspnœa diminished. Patient feels well and more active. Pulse-rate unchanged but quality much improved.

CASE 7.—Patient, aged 85. Myocardial degeneration. Pulse accelerated, irregular. Intravenous injection of 1 c.cm. P. Result: Immediate improvement. Pulse becomes at once fuller, slower, and more regular. Continued injections of P. for a longer period of time result in decided and continued improvement.

CASE 8.—A. K., aged 35, brought in cyanosed and in a dying condition. Pulse quick and hardly perceptible. Intravenous injection of 1 c.cm. P. Heart action revived immediately. After a second injection further improvement, and finally normal circulation attained.

CASE 9.—Man, aged 50. Heart insufficiency (failure) following profuse pulmonary hæmorrhage. Intravenous injection of 1 c.cm. P. resulted in immediate improvement of collapsed condition. Pulse becomes stronger and fuller. Circulation equally improved.

PS.—Since this article was written favourable results on the use of P. in surgical cases have been reported from the surgical clinic of the University of Heidelberg (*Münchener Medizinische Wochnschrift*, No. 14, p. 562, 1925).

"SMALARINA" IN MALARIA.[1]

BY GEORGE C. LOW, M.D. EDIN., F.R.C.P. LOND.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES;
AND
A. L. GREGG, M.D., M.CH. DUB.,
LATE MEDICAL SUPERINTENDENT, HOSPITAL FOR TROPICAL DISEASES.

THROUGH the kindness of Sir Ronald Ross our attention was drawn to some literature on the treatment of malaria by Prof. Cremonese's preparation of mercury sold under the name of "Smalarina." We therefore decided to give three patients suffering from malaria the opportunity of being treated with the drug.

"Smalarina" ($C_8H_{13}O_7N_4HgSb$) is put up in the form of small white tablets, and is administered before breakfast on an empty stomach. The course starts with a dose of one tablet, and successive doses are given on alternate days, increasing the amount by one tablet each time until the maximum dose of 16 tablets given on the thirty-second day completes the treatment. To give the treatment every chance, the patients were kept in bed throughout—two of them, indeed, were unfit to be up—but in spite of this the drug had no effect on the fever, nor did it abolish the parasites or change their appearance in any way. One patient had benign tertian, two malignant tertian.

CASE 1.—Male, aged 40. Returned from East Africa in November, 1924. Admitted to hospital, Dec. 8th, 1924. Had suffered off and on from malaria; present attack began six weeks prior to admission. Had been ineffectually treated with quinine.

Condition on Admission.—Ill and anæmic; vomiting; perspiring very freely; very weak; temp. 100·2° F. Spleen

---

[1] A paper read at the meeting of the Royal Society of Tropical Medicine and Hygiene on June 18th, 1925.

2½ inches below costal margin. Cardiac tone poor; otherwise systems normal.

Blood Examination.—R.B.C. 2,810,000. Hæmoglobin 50 per cent. W.R. negative. Malignant tertian rings present.

Progress.—One injection of quinine had to be given and this stopped the vomiting, causing the parasites to disappear and improving the general condition. This state was maintained until two days before the mercurial course was finished, when a relapse occurred. Vomiting restarted, parasites were again seen, and the spleen was still a full inch below costal margin. At the end of the course the usual quinine and arsenic treatment was given, with the usual spectacular result, the patient becoming convalescent in a few days. The splenic enlargement rapidly disappeared, parasites were no longer found, and the erythrocytes soon lost the polychromatophilic and basophilic degeneration, which was exceptionally well marked at the beginning. The details are tabulated for convenience in Table I. :—

Remarks.—Dec. 10th, 1924 : Intramuscular injection of quinine gr. v. 14th to 28th : Blood shows marked polychromatophilia, &c. 30th : Slightly improved.

Jan. 5th, 1925 : Blood picture improved. 7th : Vomiting and drowsy. 9th : Injection of quinine gr. 7. 10th : Oral quinine, gr. 10 t.i.d. 21st : Allowed up. 23rd : Further progress rapid. Discharged in excellent condition on Feb. 3rd.

CASE 2.—Male, aged 23. Contracted fever in Karachi in October, 1924, and had been poorly off and on since ; had taken occasional doses of quinine. Admitted to hospital Dec. 9th, 1924.

Condition on Admission.—General nutrition good, rather nervous, and tremor of tongue was noted. Chief complaint headaches. Temp. 98·4° F. Spleen just palpable, other systems normal.

Blood Examination.—R.B.C. 3,990,000. Hæmoglobin 75 per cent. W.R. negative. Malignant tertian rings and crescents present.

Progress.—General condition remained good for a fortnight, and then, despite the fact that the course of mercurial treatment was already well advanced, a sharp rigor occurred. This was followed by remittent pyrexia, until increasing headache, drowsiness, and vomiting necessitated the administration of one 5-grain dose of quinine. At the end of the "Smalarina" course the patient was worse clinically than on admission and much weaker ; the spleen was still palpable, and parasites of perfectly normal appearance were plentiful. Quinine and arsenic treatment led to rapid convalescence. Details are given in Table II.

Remarks.—Dec. 13th, 15th, and 30th, 1924, and Jan. 3rd, 1925 : Rigor.

Jan. 10th, 1925 : Course finished. 16th : Feeling better. 20th : Allowed up. Discharged in excellent condition on Jan. 30th.

Progress.—Typical rigors on alternate days persisted for some time, and the spleen became palpable. Parasites which were sometimes numerous, persisted throughout the whole course of treatment without showing any degenerative change. Quinine and arsenic established a rapid convalescence after the Smalarina course was over. (Table III.)

It will thus be seen that :—

1. "Smalarina" was tried in one case of benign tertian and two cases of malignant tertian malaria.

2. In no case did the parasites alter or disappear for good until the usual quinine treatment was started.

3. In no case did the drug control the fever ; *per contra*, this became so grave in two cases that quinine was required.

4. "Smalarina" appeared to have absolutely no effect of a beneficial nature.

We are greatly indebted to Dr. W. E. Cooke and Mr. F. W. Foster for their skilled assistance in the blood examinations ; also to Sir Ronald Ross for giving us the drug to try.

Reference.—Monograph, "Malaria," by Prof. Guido Cremonese.

Clinical and Laboratory Notes.

A CASE OF FUNCTIONAL EPILEPTIFORM SEIZURE WITH BABINSKI REFLEX.

BY CHRISTINE SHEARER, M.B., CH.B. GLASG.,
SENIOR MEDICAL OFFICER, CASSEL HOSPITAL, SWAYLANDS, PENSHURST.

ACCORDING to Dr. F. M. R. Walshe[1] and to other neurologists, the presence of a double Babinski reflex in a patient during a fit proves that the attack is epileptic. The history of the following case may be of some interest in this connexion, as it seems to indicate either that this reflex may be associated with a convulsion of psychogenic origin or that recurrent epileptic manifestations may have a psychogenic basis.

The patient, a woman of 24, had a fit during lunch. She had finished her meal and got up from the table, and when she had taken a few steps across the room she suddenly fell and was found to be completely unconscious. She was seen almost immediately by my colleague, Dr. A. G. Duncan, who made such neurological examination as was possible and has supplied the following observations.

When seen within a minute of the onset, patient was lying motionless on her back with flushed face and lips slightly cyanosed. Respiration was a little quickened and slightly stertorous, the jaw was not clenched, and there was frothing at the mouth. The eyes were closed, there was no resistance to separation of eyelids, and conjunctival reflexes were absent ; the eyes were deviated to the left and slightly upwards, the pupils being widely dilated. The head was turned to the left but there was no tonic contraction of muscles of neck. The limbs were flaccid ; knee-jerks were both very brisk. The plantar reflex was definitely extensor on each side, and on the right side movement of the toe was accompanied by slight flexion movement at hip and knee. Pulse-rate between 70 and 80.

Within four or five minutes the patient showed signs of returning consciousness by drawing up the right leg and opening her eyes. Full consciousness was regained rapidly, and presently she smiled, and in answer to a question said that she felt all right. She made no spontaneous remark and did not appear to be confused or at all disturbed by the fact that she had been unconscious.

History.—The patient had had previous fits. There was nothing abnormal in the physical condition ; reflexes were quite normal. The first of these fits was associated with the breaking off of affectionate relationship with a friend with whom she had been living in rooms for two years, both of them doing work in the same office. Early in 1921 the friend became engaged and there followed for the patient a period of mental distress. In July it was arranged for the friend to go and spend a week-end with her fiancé's relatives. The patient was very miserable at being left alone, and her distress was increased by the fact that two nights previously she had spent an evening in the company of the engaged couple for the first time, and although she had been aware of the engagement for some time, she had not until that evening allowed herself to think of it as an actual fact. On the arranged day of parting the two friends started out to travel to town by train as usual. As soon as the patient entered the train she felt sick and hot, and at the first station the friend took her out on to the platform with the idea of taking her back to their rooms. The patient remembers quite well that she resisted the efforts of her friend, saying that she was too sick and ill to move and could not be left, and it was after 1 o'clock before she would leave the station. She was aware that by delaying long enough she might prevent her friend going for the week-end. The patient was left under the care of the landlady and the friend immediately left for her visit. The patient still remembers her intense mental agony at being left alone and also her conscious longing for complete forgetfulness. In the afternoon what was described by the landlady as a fit took place, and the patient was unconscious for several minutes. Several fits occurred that evening and during the following morning. Next day the patient was taken to a cottage hospital. She was there for a fortnight and had no attacks at all, but she says she slept nearly all the time and remembers little except her bitter annoyance with anyone who came and tried to talk to her or to wake her up to take food. She only longed to die. After leaving hospital she gave up work and went home, but still got daily letters from her friend. She had another attack two months later, associated with the fact that the anniversary of her birthday passed without any token of remembrance from her friend, whose letters also were beginning to become a little irregular. During the next two years, up till 1924, there were occasional attacks of no periodical occurrence, but always associated with some emotional stress connected with this friendship.

Treatment.—The patient came under my care six months before the present attack. The psychological meaning of the attacks was explained to her and she was urged to break off all correspondence with her friend, who had now been married for some time. This she did. At the same time all drugs were stopped. The patient had had bromide or luminal continuously during all these years. There was no recurrence of the attacks.

There was evidence that a fresh affectionate relationship had lately been established, which was just on the point of being broken off, as the patient was leaving for another part of the country, and the date of departure was just fixed on the day previous to the attack when the patient was seen by Dr. Duncan. The patient acknowledged that she had conceived the idea that she might prolong her stay at hospital by having an attack, and she was suffering at the time from acute mental pain and almost praying for unconsciousness.

The patient is an emotional girl of extremely affectionate nature, not given to outward display of feeling, and she could seldom find relief in tears. It is hard to think that this train of psychological events had no bearing on the onset of the attacks. If the presence of the extensor reflex in a patient who has just had a fit is to be considered as pathognomonic of true epilepsy, might it not be apt to be used by an observer as an excuse from the long tedious task of making a detailed psychological examination, which in this case has revealed so much material for consideration ?

BRONCHO-MEDIASTINAL FISTULA IN POTT'S DISEASE.

BY C. CAMERON, M.D., F.R.F.P.S. GLASG.,
MEDICAL SUPERINTENDENT, S.E. COUNTIES OF SCOTLAND JOINT SANATORIUM, EAST FORTUNE.

THE anatomical course that a vertebral abcesss may follow is always interesting ; but the actual evacuation of such an abscess through the respiratory tract is of sufficient rarity and interest to justify its recording. Additional interest is added to this case by the accident which led to the elucidation of the complete history.

J. P., aged 24 years, was admitted to East Fortune Sanatorium on Dec. 8th, 1924. No history of his previous health or of the condition for which he was admitted was sent with him. His own statements alone were available.

He was a hunchback, and stated that the deformity had been present from his earliest years. It had incommoded him, but had not made him an invalid. He completed a normal school course, and made his living as a clerk, working until the latter part of 1923, when, without any previous pain, a swelling appeared in the upper part of the right thigh. He was admitted to the Deaconess Hospital in Edinburgh in February, 1924. The swelling was incised and pus evacuated. The wound had not healed. Such was the narrative given by him.

---

[1] THE LANCET, Jan. 10th, 1925, p. 65.

Examination.—A large diffuse kyphosis was present involving the whole of the dorsal area of the spine. The curvature was rigid, apparently of long duration, and free from tenderness and pain. In the upper part of the right thigh, at the base of Scarpa's triangle, and lying to the inner side of the track of the femoral vessels, there was a partly healed scar 1½ inches in length, with a sinus at its lower end discharging yellow pus in moderate quantity. It could be expressed from the region of the lesser trochanter, but pressure on the iliacus and psoas muscle areas did not produce any discharge. The signs suggested that the crural portion of a psoas track had persisted as a sinus. The institution X ray outfit had not been installed and examination by these means was not possible. The chest was grossly deformed. There was flattening of the percussion note over both upper lobes anteriorly, and a profusion of dry crepitant râles in the region of the left nipple. He had no cough and no spit.

Treatment.—It was decided to treat the apparently residual sinus with injections of Calot's paste, and on Jan. 23rd, 1925, 10 c.cm. were injected. The injection caused ballooning of the area which lay between the sinus opening and the lesser trochanter. Similar injections were repeated on Jan. 27th and 31st.

It was evident that the track had a greater capacity than 10 c.cm., and on Feb. 4th 20 c.cm. were injected. He experienced some abdominal discomfort during the injection of the second portion of 10 c.cm. and had an unpleasant feeling of something trickling under the lower ribs of the right side. These sensations were not mentioned by him at the time. Within a few seconds of the withdrawal of the syringe (urethral) he felt sick, became pallid, sweated profusely, and complained of a taste of iodoform in his mouth. A sensation of distressing tightness was experienced over the lower ribs of the right side. A few minutes later he began to cough up frothy white fluid, and about six minutes after the completion of the injection spat forth a yellow plug of the paste, to his great relief. With the onset of the first symptoms as much of the liquid paste as could be obtained was rapidly expressed from the sinus. During the remainder of that day, and during the day following, intermittent cough and expulsion of small plugs of the yellow paste continued. During Feb. 6th the cough subsided and the spit disappeared. No ill-effects persisted.

Specific questioning then elicited the information that before the operation in February, 1924, he had been coughing up huge quantities of pus, and that this ceased six weeks after the drainage of the abscess by the thigh.

It is difficult without radiographic examination to detect the actual diseased vertebræ, but the focus appears to have been in the mid-dorsal area of the spine. The delimitations of the various mediastinal compartments are more arbitrary than real, and the entrance of pus into the posterior mediastinum implies the possibility of spread to the superior, middle, or anterior spaces. A bronchus or the trachea had apparently been involved in the track of the abscess. A point of interest is that the comparatively small amount of 20 c.cm. of fluid injected into a sinus in the thigh should have exerted sufficient pressure to reopen this old fistula. Presumably the actual intra-abdominal psoas track was filiform.

CONGENITAL CYST OF THE COMMON BILE-DUCT.

By W. G. Wyllie, M.D. Edin., M.R.C.P. Lond.,
MEDICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

The following case of a congenital cyst of the common bile-duct was recently admitted to the above hospital, under the care of Dr. G. F. Still, to whom I am indebted for permission to make these notes.

A girl, aged 6, had a history of intermittent jaundice and abdominal swelling for one year. In the first attack sickness, diarrhœa, and slight jaundice lasted two weeks. After a period of ten months, during which she was in good health, the jaundice reappeared. A third attack of jaundice, this time associated with abdominal pain, occurred two months later, for which she was admitted to hospital. In each attack the stools were clay-coloured.

On examination jaundice of moderate intensity was present, and the superficial veins of the chest and abdominal wall were unusually obvious. The abdomen was considerably distended, and the liver was found to be enlarged and hard, its free edge reaching down midway between the umbilicus and the xiphisternum. The spleen was not palpable. Continuous with the hepatic dullness and extending downwards to about two inches below the level of the umbilicus there was a large rounded mass, which in size and firmness of consistency varied slightly from time to time. A Van den Bergh test suggested an incomplete obstruction of the bile-passages. Wassermann reaction of the blood was negative. While under observation the degree of jaundice became less. The stools were not clay-coloured, and the urine contained no bile pigments.

Operation.—An exploratory operation, performed by Mr. L. E. Barrington-Ward, disclosed a large cyst lying in apposition to the hilum of the liver. Drainage was effected and about four ounces of dark-green viscid bile evacuated. The liver was observed to be of a dark purple colour, finely granular like morocco leather on the surface, and the gall-bladder was greatly distended with dark-green bile. A transverse section of a portion of the cyst wall, examined microscopically, showed it to be composed of dense fibrous tissue with an absence of mucous membrane lining it.

After a period, during which there was a continual drainage of clear yellow bile, an operation for choledocho-duodenostomy was done. The patient died suddenly about 48 hours afterwards.

At *autopsy* the liver, cyst, duodenum, and pancreas were removed in one piece. The cyst, which had shrunk considerably, had been anastomosed to the second part of the duodenum. Both the hepatic and cystic ducts were greatly thickened and somewhat longer than usual. The proximal pole of the cyst was at the point where these two ducts unite to form the common bile-duct. The gall-bladder was normal in size but its walls were thick and fibrous. The lower end of the common duct between the cystic dilatation and the duodenum could not be traced, but must presumably have been present considering the slight degree of jaundice during life. An interesting feature of the specimen was the unusually low attachment of the pancreas to the duodenum, so that the ampulla of Vater was considerably further from the pyloric ring than it is in the normal child. The liver was slightly enlarged, of a brownish colour, firm and finely granular superficially. Microscopically there was thickening of the portal tracts. The fibrosis was specially distinct around the smaller bile-ducts and also spread into the lobules compressing the peripheral ends of the columns of hepatic cells, thus giving the appearance of pseudo-bile-ducts. The bile-ducts themselves were not dilated. Dr. Scott Williamson kindly examined the specimen and found a small slit-like dimpled orifice in the cystic swelling, which was valvular and only patent on distending the sac. He could find no connexion between this orifice and the intestine, but discovered part of a blind ascending duct, about half an inch in length, attached to the duodenal end of the pancreatic duct, which might possibly be a portion of the common duct.

In 1923 J. Morley[1] collected from the literature records of 41 cases of congenital cysts of the common bile-duct, including two cases of his own. From a study of these cases it was found that the intramural or duodenal end of the common duct was not affected, and that in all cases where it was specially looked for the portion of the common duct below the cyst was patent. The opening of the common bile-duct into the cyst was usually found on its medial aspect. In this way as the cyst distends and bulges downwards the common duct would tend to become kinked and retention of bile would occur. Only in some of the recorded cases was the liver found to be enlarged and cirrhosed. In the case described here a cirrhosis of the liver was present, secondary to the obstruction of the common duct.

---

Lewes Victoria Hospital.—So successful had been the "Penny-a-Week" Fund organised in connexion with this institution that the governors reported at their annual meeting that the fund would enable additions and alterations to be carried out much earlier than they had expected. Among these was a new and up-to-date X ray room. By means of the fund no less a sum than £711 was received during the year 1924–25. It was announced that Mr. R. F. Jowers had presented an operating table to the hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Clinical Cases.

A MEETING of this Section was held on June 12th, Sir ARNOLD LAWSON, the President, occupying the chair.

Exudate in Retina.

Dr. RAYNER BATTEN showed a man, aged 64, with a massive exudate in the right retina and some exudative changes in the left. Three years ago he had an extensive vitreous hæmorrhage in the right eye and some retinal hæmorrhages and white patches in the macular area of the left. The blood pressure was reported as varying between 85 and 135 mm. Hg. There was no albuminuria or glycosuria, the central nervous system was normal, the Wassermann negative, and there were not present the cardiovascular changes usual in retinal disease. The condition had been slowly increasing. He showed a drawing of a case of retinitis circinata, for comparison with the illustrations of this case which he projected on the screen.

Cerebral Tumour Compressing Optic Tracts.

Mr. LINDSAY REA related a fatal case of cerebral tumour which had compressed the optic tracts, chiasma, and nerves, The tumour was 40 mm. in diameter, yet the only symptom it produced was sudden blindness of the right eye. When Mr. Rea saw the patient there was the barest perception of light in that eye, but several who examined him failed to detect anything abnormal in the optic disc or in the calibre or appearance of the vessels. Neither did rhinoscopic and neurological examination give any results. A fortnight ago the speaker saw the beginnings of a papillœdema in the left disc. A skiagram revealed a flattened sella turcica. One of the sphenoidal sinuses had eroded through the bone, and two days later the man died of a spreading meningitis which had extended from the base over the brain substance. The patient had never shown any signs of nausea, and he was only giddy once momentarily. The right optic nerve had been pushed across to the left side, and the left optic nerve showed a slight papillœdema. The post-mortem examination and the drawing were made by Dr. Carnegie Dickson.

Dr. CARNEGIE DICKSON said he thought the tumour probably arose from the pituitary; the specimen had not yet been sectioned.—Dr. A. FEILING said that at the request of Mr. Rea he saw this patient early in January, and at that time he could find no reason for the loss of vision in the right eye. He presented none of the symptoms of an intracranial lesion, nor anything suggestive of endocrine disturbance. In fact, he raised the question whether the alleged loss of vision was genuine.—Mr. FRANK JULER asked whether there were pupil changes in the early stages of the case. Four or five months was a long interval before optic atrophy took place.—Mr. J. H. FISHER discussed the probable causation, expressing the view that there might have been no obvious or gross erosion of the sella turcica, but that there was an unusual anatomical arrangement of the cavernous sinus on the right side which enabled the growth to extend without much opposition. There was gross stretching of the right optic nerve, and this stretching had probably produced the early blindness, rather than a compression of those fibres between the tumour and any bony structure at the base of the skull.

Mr. REA replied that originally the optic nerves were in their proper anatomical relationship, but the sella turcica was eroded and flat. There was no disturbance of the visual field in the left eye, and there had been no approach to hemianopia in the good eye.

Pulsating Exophthalmos.—Epibulbar Sarcoma.

Mr. A. E. A. LOOSELY showed a patient with a pulsating exophthalmos. When he saw the case there was a history of six months' diplopia and weakness of the external and inferior recti. In each eye the vision was 6/6 with correction. When he saw the case a fortnight later the eye was protruded and the lids were so brawny that the eye could not be seen. There was a bruit, which could be heard by others as well as by the patient. The condition had developed in less than a week. Three days later a surgeon tied the external and internal carotids, with much benefit.

Mr. GEOFFREY VINER showed a woman, aged 31, who had complained of a black spot in the left eye, which had been increasing in size for nine months. He based his diagnosis of epibulbar sarcoma chiefly on the result of the slit-lamp examination. This showed that the pigmentation was extending not only on to the cornea, but also to the substantia propria.

Sir JOHN PARSONS considered the lesion was probably a pigmented nævus or mole of the conjunctiva. It was very unusual for these to become malignant. Still, there were several peculiarities in the case which required caution, and he suggested removal of the superficial layers of the cornea and microscopical examination of them before deciding on anything radical.—Mr. ERNEST CLARKE agreed with Sir John Parsons.

The Operative Treatment of Dacryocystitis.

Mr. G. H. POOLEY (Sheffield) read a paper on this subject. He said that in a large industrial area, like that of Sheffield, a large number of cases of dacryocystitis presented themselves for treatment, and as some came considerable distances and had household and other duties to attend to they could not be dealt with as out-patients. The condition was commoner in women than in men, in the proportion of about 4 to 1. The defects to be dealt with might be classified as follows: Stenosis of the puncta; stenosis of the canaliculi just before they joined the sac; obstruction in the sac itself without retention or regurgitation of inflammatory products; obstruction with retention of inflammatory products which, on digital pressure, passed down into the nose; and obstruction in which the inflammatory products passed, on pressure, up through the puncta into the conjunctival sac. In all these cases inflammation seemed to be confined to the interior of the sac. In a large and more serious group the tissues round the sac became acutely inflamed, and in many there was an abscess formation and death of bone. Many of these presented large red swellings. Sometimes these latter had burst externally before an ophthalmic surgeon saw the case. Obstruction of the sac without regurgitation could be kept quiet without operation. When the contents could be squeezed down into the nose all that was required was repeated digital pressure by the patient, combined with the use of antiseptic lotions. Distensions of the sac with regurgitations on pressure could be incised after injection with an antiseptic dye. A permanent drain inserted into the middle meatus of the nose prevented epiphora. Most trouble was caused by the suppurative cases. For some time he was content to incise and drain these cases, after which they were fomented. The results were fairly satisfactory, but in many patients abscesses subsequently formed, probably occasioned by dead bone. Next he tried incision of the inflamed sac, removal of the lacrymal ethmoidal cells, and scraping of the duct. This gave fairly good results, and many of the patients were free of epiphora: but some were troubled by it. There was no epiphora in the cases in which he had made a free opening into the nose. Then he commenced making an opening through the sac into the middle meatus of the nose, scraping out the sac and granulations, and leaving a ribbon of gauze in for three days. On the removal of that, two fishing-gut sutures which had been inserted at the time of the operation and left unfastened were tied, and the edges of the skin brought together. This operation only took two or three minutes to perform, the results were satisfactory, and the convalescence was rapid. Fluid was syringed through the lower punctum into the nose on the seventh day, and on each subsequent day until the patient went home. He also described a further development of his technique, which had yielded excellent results, as there was no deformity and little or no epiphora. The ages of the patients on whom he had done these operations ranged from 18 months to 76 years. His series included two deaths—one from mycocarditis during recovery from the anæsthetic, and the other from a septic meningitis which had commenced before the operation was undertaken.

Mr. W. B. OLIVER suggested skin-grafting with the use of dentists' wax to take the place of catgut sutures.—Mr. FISHER said he thought epiphora must still exist after Mr. Pooley's operation; and Mr. Oliver's suggestion seemed unlikely to improve Mr. Pooley's operative procedure.—The PRESIDENT said he had not found that the epiphora was cured by removal of the sac. In most cases the suppuration and sepsis could be got rid of, but the epiphora remained.—Mr. E. D. DAVIS said that the chronic cases in which the canaliculus was slit up or an external operation done apart from excision of the sac had been a failure. There seemed a danger of the formation of a fistula from the nose to the face after Mr. Pooley's operation. He had seen two or three such results, the mucus coming on to the face.—Sir JOHN PARSONS pointed out that mucocele did not require the type of operation which Mr. Pooley had described. When the excretory channels had been obliterated one could not expect the patient to be free of occasional epiphora afterwards. In most cases in which West's operation had been done the opening rapidly closed up and the patient was no better off than before.—Mr. AFFLECK GREEVES said he would have thought that an opening into the nose was to be avoided; he had seen two cases in which after such an opening there was a general infection of the ethmoid cells, and the patient had a chronic fistula, which was only ended by a radical operation.

Safety Limits of the Jullundur Operation for Cataract Extraction.

Dr. G. MONTAGU HARSTON gave a short communication on what he considered to be the safety limits of the Jullundur operation for the intracapsular extraction of cataract. The crux of the matter was that the operation should not be done when the tension was high; even one millimetre extra pressure at the time the operation was done might mean disaster. A further point was that he was sure he could do the intracapsular operation far more easily with his fingers than by means of the Barraquer apparatus.

Sir JOHN PARSONS said he thought these intracapsular methods must necessarily be accompanied, in their present stage, by increased dangers to the patient's eye, and that they were not, therefore, fully justifiable.—The PRESIDENT also discussed the operation.

CARDIFF MEDICAL SOCIETY.

AT a recent meeting of this Society, Dr. E. E. BRIERLEY, the President, in the chair, Dr. D. LLEWELYN WILLIAMS, together with Dr. COLSTON WILLIAMS and Dr. RALPH PICKEN, opened a discussion on the

Provision of Hospital Accommodation.

Dr. Picken's remarks were confined to the question of hospital accommodation in Cardiff and East Glamorgan, and immediate steps which might be taken to relieve the existing pressure on the voluntary hospitals.

Voluntary Hospitals.—The population of this area, he said, was approximately 800,000, and voluntary hospital beds numbered about 850, or a little over 1 per 1000. These were distributed as follows: Cardiff 460 (Cardiff Royal Infirmary 341), other districts 390. Beds in near prospect at Cardiff Royal Infirmary 60–80. Beds in remote prospect at Prince of Wales's Hospital 100, elsewhere 240. Limit of prospective accommodation about 400 beds. The requirements as estimated by the hospitals themselves were: Cardiff Royal Infirmary (waiting-list 1800–2000) 216 beds, others vague. On a conservative standard of 2 beds per 1000, 750 beds were required for the whole area. If a higher standard of 3 per 1000 were adopted, the beds required would be 1550.

Poor-law Hospitals.—The total number of Poor-law beds in East Glamorgan was about 1100 (Cardiff 260, elsewhere 840). Many of these were permanently required for aged and infirm, and some of the institutions were not easily adaptable to modern scientific hospital methods. New beds in prospect numbered 650 (Cardiff 450, elsewhere 200), most of which would probably be excellent accommodation but ill-distributed to suit the areas whose needs were greatest. The projected accommodation in Cardiff requires to be reconsidered in relation to the future of the medical school.

Dr. Picken said that ambitious schemes were impracticable because of the enormous expenditure involved. The best use ought to be made of fever hospital accommodation (at present under-taxed) in populous areas—e.g., for acute pneumonia. Authorities responsible for tuberculosis should be encouraged and helped by the Government to provide adequate accommodation. Voluntary funds were not likely to be forthcoming in sufficient volume and voluntary hospitals were naturally reluctant to accept the control associated with rate- or State-aid. The most practicable measure appears to be the encouragement of the Poor-law authorities to develop their institutions to meet the needs of carefully defined areas. Subsidy from the Government and coördination through the Ministry of Health are probably required, involving legislation. If this policy were adopted an improved standard of staffing and medical equipment would be necessary. Health authorities, including county councils, should be encouraged to provide beds truly preventive in character—e.g., antenatal and maternity, infant wards, and open-air residential schools which ought to be available for teaching purposes and research. The analogy of the influence of sanitation on the beds needed for typhoid or of child welfare schemes on infant mortality suggests that such provision may materially affect the need for hospital accommodation for the next generation.

Dr. COLSTON WILLIAMS sketched briefly the history of hospital provision in this country. He illustrated the imperfections of local provision and its failure to keep pace with the rapid growth of population. He then traced the growth of the power of local authorities to provide bed accommodation for special diseases. He summarised some of the major defects of local provision revealed by the inquiry of the Voluntary Hospital Subcommittee in South Wales. The argument he then developed was that the medical profession should take every step in its power to assist the public in providing, not merely beds, but a fully equipped, coördinated, scientific service, and use it for the application of modern science in the prevention and cure of disease. He expressed doubt whether, in view of the present national conditions, voluntary hospital provision could adequately meet the needs of the future, and that the existing and future modifications of Poor-law hospital accommodation with improved service might materially help to solve the problem. In attempting a solution of the problem it was desirable, he said, to consider the great need of the middle class for obtaining skilled nursing, surgery, and expert opinion within their financial ability, and a middle way might be found in the hospital policy of the association, which was intended to remunerate hospital staffs for services which could not be equitably demanded from them except in the service of the poor. The general local needs which were imperfectly met in South Wales were beds for medical cases, particularly for females and children, an increased number of special department beds for orthopædics, diseases of the eye, ear, nose, and throat. In conclusion of a general review on local provision, he showed that it was, as a whole, a striking example of confused, uncoördinated effort resulting in much waste of money and inefficiency of service. It was a duty of the medical profession to help at this juncture, and if they gave of their best to the community they need not fear in respect of their dignity, status, or remuneration.

Dr. Llewelyn Williams said that the voluntary hospitals were hardly able to carry on in 1920 and 1921 and appealed to the Government to give them financial aid to help them out of their difficulties. A Government grant of £500,000 was made to these hospitals to prevent disaster. This money was distributed through local voluntary hospital committees. The distribution of this grant was completed by March 31st, 1924. The total grant for Wales was £22,098, and of this sum Glamorgan received £15,522. If we were all agreed that the voluntary system should be maintained, he asked what steps should be taken to provide these hospitals with an adequate income? Provision had already been made by the State and local authorities for persons suffering from diseases that were considered to be a danger to the community—infectious diseases, venereal diseases, and tuberculosis. Provision would also be made for crippled children up to the time they left school. Maternity hospitals also received considerable help. Nevertheless, the problem of funds was still, and always would be, formidable. An important factor, bearing on the possibility of continuing the voluntary system, was the very marked increase which has taken place in recent years in workpeople's contributions; further, there might be a possibility of extending the National Insurance Act to include hospital treatment. The alternative was assistance by central grant or local rates, with the necessary corollary of participation in administration. There was one defect in the voluntary system, he said—namely, the want of coöperation between existing hospitals; they were not part of a connected system. The smaller hospitals should be linked up with the big hospitals and used as casualty clearing stations, and possibly recovery beds. Until these hospitals were brought into some definite relationship with the big city hospitals, they were not used to the best advantage.

With regard to the relation between voluntary hospitals and Poor-law hospitals, speaking broadly, the voluntary hospital should deal with the acute case requiring specialised surgical or medical treatment, while the Poor-law hospital should deal primarily with the case in which the main need was skilled nursing and the kind of attention which cannot be given in the patient's own home. If we accept this principle, we should have to face the difficulty that a hospital could not concentrate entirely on the treatment of "chronics" without prejudicing the efficiency of the medical and nursing staffs. It was, however, essential that the voluntary and Poor-law hospitals should to some extent work together.

He was inclined to the view that the *local* hospitals should, as regards medical staff, be open to the medical men practising in that district, and should not be limited to a number of men, who are not necessarily the best men. There is a great deal to be said for admitting every doctor in the area who is prepared to take his share of the hospital work. At the same time, it would be a great advantage if physicians and surgeons of consultant rank from the large hospital were appointed as consultants to the local hospitals; further, it is the obvious duty of a hospital like the Cardiff Royal Infirmary that it should develop into a centre for post-graduate teaching and research work for the surrounding neighbourhood.

The following took part in the discussion: Dr. Bruce Low, Prof. A. W. Sheen, Dr. D. R. Paterson, Mr. H. G. Cook, Dr. Ivor J. Davies, Mr. T. E. Hammond, Dr. J. O'Flynn, and Dr. Melbourne Thomas.

Reviews and Notices of Books.

Manson's Tropical Diseases.

A Manual of the Diseases of Warm Climates. Eighth edition, revised. Edited by Philip H. Manson-Bahr, D.S.O., M.D., D.T.M. & H. Camb., F.R.C.P. Lond., Physician to the Hospital for Tropical Diseases, London, and the Albert Dock Hospital. London: Cassell and Company, Ltd. 1925. Pp. 895. 31*s.* 6*d.*

Since the last edition of this book in 1921 the medical profession and that section of it particularly dealing with tropical medicine has had to deplore the death of its original author, Sir Patrick Manson. The eighth edition, which now appears, has been drastically revised; much new material, both in the text and as illustrations, has been introduced without, however, adding to the size of the book, which is actually shorter by some 70 pages. The practitioner in the tropics has often to be a jack-of-all-trades. He must be a clinician with not only a knowledge of the special diseases occurring in tropical countries but also of those commoner in temperate climates. For example, when considering the diagnosis of a fever, as is pointed out in a very interesting chapter on this subject, he must keep in mind the possibility of pulmonary tuberculosis, as well as the various suppurative conditions, while the curious periodic fever met with in the Pel-Ebstein type of lymphadenoma may also add to his diagnostic difficulties. Moreover, the practitioner in the tropics is frequently his own pathologist; in Section B of the appendix some 40 pages of small print and many illustrations give as good and as practical an account of the chief laboratory methods he is likely to have to employ as many a text-book of much greater size. In tropical regions, again, the subject of medical zoology becomes of great importance and the bulk of the appendix is devoted to this subject. This section has been completely rewritten for this edition and contains many new illustrations. Here it is especially praiseworthy to produce a readable narrative, for the nomenclature, already almost terrifying by reason of the multiplicity of types and species, is rendered even more confusing by the number of synonyms in existence. Some trematodes, for example, have as many as seven or eight scientific names, only one of which can presumably be valid under the rules laid down by the various international congresses. An entirely new feature of the present volume is the inclusion of six maps, which show the geographical distribution of trypanosomiasis, leishmaniasis, yellow fever, schistosomiasis, and filariasis.

This is a very useful addition to what is well recognised as a most valuable standard text-book on tropical diseases.

Physiological Methods.

Handbuch der Biologischen Arbeitsmethoden, herausgegeben Geh. Med. Rat. Prof. Dr. Emil Abderhalden. Berlin: Urban und Schwarzenberg. 1923–24–25.

It is difficult to give an adequate account of a publication appearing, as this one, in a number of small parts, not always complete in themselves. We have received enough parts to be assured of the comprehensive nature of the work and of the laborious care which has been taken to ensure accuracy in detail as well as general perspective. It covers a wide range. For example, Lieferung 101 deals with every conceivable method of investigating the urine, and the matter is presented with laborious detail. Lief. 107 is concerned with the biological examination of certain food substances, honey, artificial sweetening agents, and sugar. In the 73 pages devoted to honey Dr. E. Spaeth records a striking amount of research into this substance; it would seem that honey might prove to be of great use in medicine if the knowledge contained in this volume were more widely known. The section dealing with the saccharine group is very brief, but the final part, on sugars, is complete and well written. Lief. 108 gives a summary of the standard methods employed in Germany for the investigation of the physical standards of school-children. Lief. 109 contains an excellent account of histological techniques, given in great detail, with full references. Of especial value are the sections dealing with the histo-chemical methods for demonstrating inorganic tissue substances and for showing such bodies as mitochondria. Lief. 110 is the terminal part of the section on embryology, wherein Prof. Roux writes on the more mechanical methods of investigating development and Prof. Godlewski on special problems connected with fertilisation. A third small section on chemical problems by Prof. Parnas is too intensely specialised to make any general appeal. Lief. 114 provides an accurate and clear description of methods of estimating inorganic constituents of the blood, together with detailed considerations of the organic constituents and the formed elements. This part is marked by a breadth of outlook not found in some of the other sections; the best methods have been selected regardless of nationality, and the volume is thoroughly useful. Lief. 132 contains a full and lucid account of the theory of cystoscopy; the practical aspect is less satisfactory. Lief. 136 consists of the end of the section on fungi and a description of laboratory methods. The recent advances in this department are not included. Lief. 137 deals with diphtheritic skin reactions and is written by Dr. Schick and others. It shows an absence of criticism of the tests described and some lack of appreciation of work done in other countries. Lief. 139 forms part of the section on experimental psychology, and deals with the influence of environment. The handling of the subject, so far as this incomplete excerpt goes, seems clear and logical. Lief. 140 is concerned with histological methods; there are some notable omissions, such as the method of demonstrating pancreatic lesions in diabetics, Lief. 141 deals with the general methods of estimating energy balance and provides detailed accounts of methods of obtaining specimens from and of finding the basal metabolism in infants. The account of metabolic exchanges is somewhat complicated. Lief. 142 is occupied by a description of the methods of investigating the gas exchange of various animals and man. It is written by Dr. F. G. Benedict and is a fine piece of work, constituting one of the most up-to-date and detailed accounts of the subject which has appeared. Lief. 143 is concerned with joint function, developed into a highly mathematical science, and is an excellent example of the extent to which simple truths can be shrouded in unintelligible mathematical formulæ. The second part deals with graphic methods of studying movements. Lief. 152 consists mainly of a catalogue of apparatus used in investigating muscle sense and reciprocal innervation.

The "Biologischen Arbeitsmethoden" has been recognised in all countries as being an excellent system of physiological methods, and in its complete form should prove a most valuable addition to libraries of pathologists and physiologists.

MEDICAL GYNÆCOLOGY.

Fourth edition. By Samuel Wyllis Bandler, M.D., Professor of Gynæcology in the New York Post-Graduate Medical School and Hospital. London and Philadelphia: W. B. Saunders Company, Ltd. 1924. Thoroughly revised, with original illustrations. Pp. 930. 40*s.*

A comprehensive revision has been carried out in this edition. Several chapters have been rewritten and the new matter inserted includes an excellent description of the technique employed by Rubin in testing the patency of the Fallopian tubes by transuterine insufflation. The section dealing with the therapeutic uses and methods of employing radium is also fresh and is well worth reading. Pronounced anæmia, impaired renal function, and abnormal retention of nitrogenous waste products are all considered contra-indications for its employment.

Under the title "Methods Employed in Medical Treatment," Dr. Bandler discusses a variety of therapeutic measures such as hydro-therapy, electrotherapy, and curettage. The latter procedure can hardly be classed as medical, and the disadvantages of any attempts to demarcate gynæcology into medical and surgical compartments are once more exemplified. This difficulty arises throughout the book, much space being devoted to discussing such pathological conditions as chorion-epithelioma, ectopic gestation and ovarian cysts, the treatment of which is obviously surgical. The indications given for the employment of electro-therapy are many and varied, but the most startling is in the treatment of dysmenorrhœa by use of intra-uterine electrodes—either galvanism or faradism being employed. No mention is made whether an anæsthetic is administered or not. As in previous editions of this work, a comprehensive and lucid account is given of the action of the endocrine glands and their close inter-relationship with the female genital tract and the autonomic nervous system. Diabetes and insulin treatment are now included in this portion of the book, and the probable relationship of the pancreas to hyper-thyroidism and Graves's disease is also discussed. Dr. Bandler himself has rewritten this section, which is up to date and represents an immense amount of labour and research into literature. The names of the various authors of recent work are freely quoted; unfortunately numbered references to the various contributions are omitted.

In view of the hypothetical nature of many of the views expressed and treatments recommended, this work cannot be considered a suitable text-book for the student or young practitioner, but for those of ripe experience with powers of discrimination we can cordially recommend it. The subject-matter is lucidly expressed, the printing is good, and the format is excellent. The book contains a wealth of therapeutic measures for the treatment of female diseases and also one of the clearest expositions of endocrinology as applied to gynæcology that we have seen.

PHYSICS.

Elementary Physics. For Medical, First Year University Science Students and General Use in Schools. By G. Stead, M.A., Reader in Physics, Guy's Hospital Medical School. London: J. and A. Churchill. 1924. Pp. 453. 10*s.* 6*d.*

Dr. Stead has written a useful book on elementary physics, drawing upon his experience as a teacher of medical students. The book is singularly complete in its range of data; the illustrations are excellent, and most of the chapters are finished off with a list of those numerical examples which most medical students find so difficult to master. Samples of examination paper questions are included. The chapter on sound is particularly good, difficult points being carefully explained. In fact, the whole of the book is so clear that it should make a strong appeal to the medical student.

The Ideal Aim of Physical Science. By E. W. Hobson, Sc.D., LL.D., F.R.S., Sadlerian Professor of Pure Mathematics. Cambridge University Press. 1925. Pp. 34. 2*s.*

The author of this address advocates that physics should be looked upon as a descriptive science. Arguing with the precision habitual to mathematicians, he shows how the "explanatory" school simply shift the burden on to other shoulders, since the stage is inevitably reached when explanations fail. A teacher is on surer ground with descriptive ideals before him and the problems to be tackled are no less exacting. Prof. Hobson is really illuminating; a few pages from his pen on the relativity ideas of Einstein and Minkowski are worth volumes from those who have not grasped the essentials. We may quote a passage to illustrate the incisive way in which he deals with crucial problems.

> "Matter, as revealed by its gravitational phenomena, manifests itself solely as a system of singularities in the metric system. There is no place left for the notion of substance, either material or ethereal. It is sometimes said that space-time is crinkled or warped; this statement is liable to produce misunderstanding, at least when it is not properly qualified, and is in any case quite inappropriate. The fundamental manifold has no properties intrinsic to itself, except that of being ordered in accordance with an abstract conception of order. Hence it has no singularities which could be described as crinkles or warps. The singularities by which matter is manifested belong to the metric imposed upon the fundamental manifold from without, and are not intrinsic to the manifold itself."

This little brochure is a model exposition of constructive criticism.

Joule and the Study of Energy. By ALEX. WOOD, M.A., D.Sc., Fellow and Tutor of Emmanuel College and Lecturer in Experimental Physics in the University of Cambridge. London: G. Bell and Sons, Ltd. 1925. Pp. 88. 1*s.* 6*d.*

THE aim of the excellent series of "Classics of Scientific Method" is—

> "to provide reproductions of the greater masterpieces of Science in convenient forms, together with a complete account of the action and reaction of ideas which, through the process of time, led up to the crucial experiments carried out and described by some great master."

Dr. Wood has well realised this aim, and Joule and the Study of Energy is an excellent selection for illustration. Dr. Wood takes the reader through the days spent by investigators in their search for perpetual motion, an idea so deeply ingrained that the failures of others only seemed to add zest to the pursuit. So much ingenuity but so little knowledge! Galileo's contribution to mechanical knowledge probably did more than anything to divert people from this vain quest. The bulk of this book is devoted to an account of Joule's life work. It is a fascinating record and brings before the reader the debt that science owes to a man of amazing accuracy. Finally, Dr. Wood gives a brief review of natural sources of energy in which he dwells for a moment upon the stories of atomic energy which await release.

QUANTITATIVE ANALYSIS.

The Theory of Quantitative Analysis and Its Practical Application. By HENRY BASSETT, D.Sc., Ph.D. London: George Routledge and Sons, Ltd. 1925. Pp. 308. 15*s.*

IN the past analytical methods have in the main been developed empirically, and it remains to be seen whether this state of affairs will alter in the future. In the preface to this book it is stated that in most cases, now that theoretical knowledge has advanced sufficiently, it is possible to interpret the operations of quantitative analysis in terms of the general chemical laws, and to develop new methods, if need be, by their help, instead of empirically. Dr. Bassett explains that no attempt has been made to write a complete treatise on quantitative analysis, a stop having been made at the consideration of the physico-chemical principles at the base of analytical operations. Accordingly he has included chapters on electro-affinity, coördination and solubility, and complex-ion formation. The book throughout bears the imprint of being written by an enthusiast, but perusal of its pages leaves us doubtful whether much is gained by the author's method of treatment. The average person making use of quantitative analysis for a definite purpose is more concerned with the exact conditions for effecting his purpose with accuracy than with the elaborate interpretation of these methods in terms of mass action, solubility products, and so forth. There may well be a public for the book, but it will not, we believe, be drawn from the ranks of those engaged in chemical analysis.

GYNÆCOLOGICAL NURSING.

Gynæcology for Nurses and Gynæcological Nursing. Fourth edition. By COMYNS BERKELEY, M.D., M.C. Cantab., F.R.C.P. Lond., Gynæcological and Obstetric Surgeon to the Middlesex Hospital. London: Scientific Press. Ltd. 1925. Pp. 364. 7*s.* 6*d.*

A COMPLETELY revised and enlarged fourth edition of this handbook for nurses has just been issued under the auspices of the Press Committee of the Middlesex Hospital. It has been written for nurses preparing for the State examination, and new matter is inserted so as to include the subjects dealt with in the part of the advisory syllabus issued by the General Nursing Council which relates to gynæcology.

The book admirably fulfils the requirements of the State examination in every way, and in addition contains a fund of practical information on gynæcological nursing which is not usually obtained even in text-books of a more pretentious character. Comprehensive directions are set forth in regard to the technique the nurse should employ in preparing for, or assisting at, an operation in hospital and private practice. We particularly like the useful illustrations with accompanying lists depicted in Chapter XXIII., where those instruments are enumerated which may be required for the various gynæcological operations.

The volume is well printed and illustrated, and should become a standard text-book for the nursing profession.

HEALTH AND PERSONALITY.

By JOHN S. GRIFFITHS, M.R.C.S., L.R.C.P., D.L. Library of Philosophy and Religion. London: Hodder and Stoughton. 1925. Pp. 320. 6*s.*

DR. Griffiths has a sense of beauty and a firm hold on ultimate values; much of what he says is of value and some is original. But, as often happens with "popular" works, the lack of system in his presentation makes it difficult for the reader to keep his attention on the book. The five chapters form a series of short lectures on unrelated topics. The author dislikes modern psychology and agrees with a recent ex cathedra statement that "dreams have no psychological significance." Even those who are disinclined to accept this or certain other opinions will appreciate the general wholesome tone of the book.

RACIAL CHARACTERISTICS.

Rassenkunde des deutschen Volkes. Sixth edition. By Dr. HANS GÜNTHER. Munich: J. F. Lehmann. 1924. Pp. 504. 16*s.* 3*d.*

THAT this work has run through six editions in two years is sufficient proof of its popularity. It is, as its name denotes, a description of the characteristics of those races which constitute the population of Germany. The text has been rewritten and numerous excellent illustrations are added. The author, after a two years' residence in Scandinavia and Eastern Germany, has succeeded in further refining his previous classification of the races of Europe; he has now added a fifth race, the East Baltic, whose chief characteristics are: "Short stature, short head, broad face, flat nose, light eyes (slightly Mongolian), and fair hair." Dr. Günther claims, therefore, that he has discovered two fair European races—the Northern or Teutonic (tall, long-headed, and narrow face), and the North-Eastern or East Baltic, described above. It may be noted, however, that Deniker (Races of Man), in 1900, described six European races, two of which are fair-headed—the dolichocephalic, tall Northern race, and the sub-brachycephalic, short Eastern race. Dr. Günther's book is especially commendable for its 450 excellent portraits of types, and being written in simple German will appeal to the reader who has only a passing knowledge of that language.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

EVIDENCE OF OTHER MEDICAL BODIES.

(Continued from p. 1316.)

The National Medical Union.

(App. XLIX. and Q. 15745–15989.)

EVIDENCE was given by Dr. V. T. Greenyer and Dr. Charles Comber. The National Medical Union claims to represent that considerable portion of the profession which refused service under the National Health Insurance Acts, and has maintained its objections to the insurance scheme down to the present time. It considers that its attitude has been justified by the situation from time to time revealed in the working of the Acts. The membership of the National Medical Union at the present moment is 247.

It is the view of the National Medical Union that there should be a State medical service for necessitous persons, but that the insured person, as he exists under the National Health Insurance Acts, being in no sense a necessitous or destitute person, should insure voluntarily under one or other of the insurance societies under the supervision of the Registrar of Friendly Societies, which well served the purposes of medical benefit before the present National Health Insurance scheme became enacted.

With regard to the administration of medical benefit, the evidence suggests that :—

> The medical and lay committees and mixed professional and lay assessorships of the National Health Insurance Acts, with above all the absolute and grotesque power placed in the hands of the Minister of Health, have degraded a liberal profession to the level of a supervised trade and deprived all accepting it of that responsible sense of self-respect once the essential feature of a free profession.

In support of the Union's statement that a circular letter which it had issued, containing a declaration of the essence of the Union's policy, had received the assent of a large section of the medical profession, the witnesses explained that the circular letter was sent only to London doctors as a test. It produced 1333 replies, of which 97 per cent. were favourable.

With regard to the restriction of medical treatment under the Insurance Acts by the exclusion of those services involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess, the witnesses said :—

> (Q. 15775.) We are not divided into classes, and we are not expected to have the type of knowledge which would suit this particular definition ; so that when we approach a patient we approach him with all our knowledge, and it seems to us that when you attempt to limit by some definition of this character what shall be the range of treatment, you are giving us something to understand which we cannot intelligently apply to our system of education. I am speaking for the profession now.

It was contended that there was competition amongst panel doctors which was degrading and offensive. With regard to this, Dr. Comber said that at the commencement of the Act :—

> (Q. 15791.) A lot of down-at-heel practitioners rushed on the panel before anybody else, and they are now doing pretty well.

He complained to the General Medical Council in one case and was told that there were too many cases of the sort for it to be possible to investigate. Later he agreed that the large majority of panel doctors were honourable men :—

> But you must remember that at the commencement of the Act all the rubbish went on because there was nothing to stop them.

The Scottish Medical Guild.

(App. L. and Q. 15990–16092.)

Evidence was given by Prof. William Russell and Dr. Frederick Porter, who stated that their Guild represented about 700 non-panel men in Scotland. They agreed broadly with the views expressed by the Union, though they might have stated them in a different way.

> (Q. 16065.) Do not you think a large number of the medical men in Glasgow who came under insurance service were as high in their principles as those in Edinburgh ?—I will tell you this much, if they had the high principles they would not hold them very long under the National Health Insurance system.

Prof. Russell stated :—

> (Q. 16090.) We are perfectly aware that there are many medical men on the panel who do their work most conscientiously and some men prefer that work to private practice, but our experience is (and I speak as a hospital physician as well as one coming in contact with all kinds of practitioners and people in Scotland) that a great deal of the work is eminently unsatisfactory and that there has unquestionably grown up, whether it is right or wrong that it should have grown up, a feeling amongst the people that one comes in contact with that a panel doctor will not give you as good treatment as a non-panel doctor will.

INDIVIDUAL EVIDENCE.

(App. LI. and Q. 16093–16193.) Dr. Harry Roberts (Stepney) gave first-hand evidence as a general practitioner in East London who, with three partners and an assistant, deals with a panel of nearly 10,000 insured persons. There is associated with his practice a dentist, a masseur, and two nurses. He said that patients in such a district as his have received since the passing of the Insurance Act a much improved service, consequent upon the improvement in the rate of payment up to the amount which was customary in prosperous working-class districts.

> (App. LI., 5.) An entirely new situation was created in districts like mine. I at once realised that it would now be practicable—if the bulk of my private patients remained with me as insured patients—so to reorganise my work as not only to gain greater leisure for myself, but to provide an altogether fuller medical service for my patients.

Dr. Roberts said (Q. 16102) that insured persons nowadays see much more of their doctors than they used to do, and that although perhaps in his own practice the partners did more for insured persons than they were strictly under an obligation to do, he came across panel patients of other doctors and they were entirely satisfied with the medical arrangements. He found, however, a good deal of grumbling over the money benefits.

> (App. LI., 7.) I have never heard an insured person speak of his approved society in a filial spirit. When he has any picture of it at all it is generally as a kind of blend of Scotland Yard and the board of guardians.

He found amongst insured persons generally a complete ignorance not only of the general principles of insurance and of the Health Insurance Act, but of the regulations of the societies, and consequently of the rights and benefits to which they are entitled, and of the penalties to which they are subject, and how those penalties may be avoided. They do not know when they are entitled to medical benefit—for many of them do not receive medical cards until they make individual application for them—nor under what conditions they will cease to be entitled.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8); Evidence of Various Approved Societies (May 30th, pp. 1135–6); Evidence of the British Medical Association (June 6th, pp. 1184–6; June 13th, pp. 1248–50; June 20th, pp. 1315–6); Evidence of other Medical Bodies (June 20th, p. 1316).

The witness criticised severely the form of record prescribed by the Ministry of Health, and said that although in his practice they kept a full-time secretary whose job it was to write up the official records, he and his partners never used them, but relied on a system of record cards which were kept in the custody of the patients themselves.

> (Q. 16113.) Everyone of our 10,000 panel patients has one: often he has a bunch of 20 record cards pinned together, which he always brings with him, and in nearly every case carries with him wherever he is. . . . Whenever he comes to the surgery he produces it immediately, almost always without being asked for it. That includes a complete list of every attendance he has had since we knew him, and the opinions which any of us have ever formed as to his ailments, and all the prescriptions which have been given to him from the beginning, together with any opinion of a consultant to whom we have sent him which may have been given to us.

Dr. Roberts said that the principal limitations of the utility of the present medical service seemed to him to be :—

> (1) The falling out of benefit of insured persons through unemployment; (2) the limitation of medical benefit to certain members of a family only . . .; (3) the limitation of provided medical treatment to such as is assumed to be within the range of an average general practitioner . . .; (4) the general neglect of insurance committees to make use of their powers to organise public education of the people in the laws and principles of health.

(App. LII.; Q. 16194–16345). Lieut.-Colonel W. Bickerton Edwards, who holds office under the Ministry of Pensions but gave evidence as a private individual, gave expression to his views as to the various ways in which the National Health Insurance scheme was defective on its medical side. Amongst other criticisms, he said that as the panel service was underpaid it induced medical men to take on more work than they could efficiently carry through. He suggested that a visiting list of 50–100 for the day over a scattered area, and 50–60 patients twice a day in the doctor's consulting rooms worked out in minutes spoke for itself. It was pointed out to the witness that on the basis of careful calculations submitted in evidence by the Ministry of Health his figures would correspond to a list of about 13,000 persons, whereas the maximum number allowed to any panel doctor was 2500, and 65 per cent. of all the panel doctors in the country have lists of less than 1200 insured persons.

Amongst the witness's proposals for an improved service, he suggested the division of the country into areas, each with an area hospital with a resident medical officer, nursing staff, and ambulance car, and each general practitioner connected with his hospital by telephone. He thought that a body of experts should report on the possibility of the pooling of the existing funds spent on the medical services of the country, and that compensation might be paid for the loss of the wage-earner by death, whether from accident or sickness, the premium at present paid for workmen's compensation being replaced by a sort of health tax. Upon it being pointed out to the witness that the Holman Gregory Committee had within the last three years examined this very proposal and reported against it, he said that he had not been aware of that fact.

(App. XXIII. and Q. 10061–10173.) Mr. Benjamin Broadbent, who, in connexion with health administration in Huddersfield has made the care of infant life his special interest, said in evidence that the cash maternity benefit under the Acts was a great opportunity unused and that its method of administration was a failure. He criticised the system of payment after the birth and the method of payment by insurance society agents in many cases who canvassed for the insurance of the child's life.

> There is no means whatever for impressing on the mothers the fact that the maternity benefit money is given to her solely in virtue of her motherhood in trust for the child, and that it is morally a fraudulent use of the money to spend it on anything that does not help her to be a better mother and to rear her child healthily. It is even open to question whether the maternity benefit has had any appreciable effect in the reduction of infantile mortality, in other words, whether it has improved motherhood.

Mr. Broadbent considered that maternity benefit should be linked up with the maternity and child welfare schemes of local authorities and the money actually distributed by the health visitors, who could couple payment with valuable advice to the mother.

PORT OF LONDON SANITARY AUTHORITY.

THE NEW MOTOR LAUNCH.

By W. M. Willoughby, M.D., D.P.H. Camb.,
MEDICAL OFFICER OF HEALTH FOR THE PORT OF LONDON.

The medical officers of the Port of London Sanitary Authority stationed at Gravesend for the purpose of preventing infectious disease entering the port on ships, as representing the medical officer of health, have somewhat plenary powers. The Port Sanitary Authorities (Infectious Diseases) Regulations, 1920, require and permit the medical officer of health to do all that is "reasonably necessary" for the prevention of the spread of infection from ship to shore. "Infection" is not defined. Seldom is any power so seemingly wide and undefined and touching such large interests conferred on one man. And yet on examination the words "reasonably necessary" imply the very best of limitations—namely, that all the medical officer does shall be "reasonable" and the thing done shall be "necessary."

Such powers and demands could only be given and made when the knowledge of cause and course of the ship-borne infectious diseases had reached a point which showed on the one hand that action taken must often be immediate, and on the other that action must be as varied as the agent of infection. These powers are the antithesis of hide-bound quarantine; they contrast cerebration and panic. Any long voyage traveller must have noticed the effects of the "blighty" sensation on passengers and crew approaching home and can imagine the result of any delay at the hand of man. Fog in the Channel, well and good, even days of it, but one hour's delay because a fellow man wishes to inquire as to the correctness of a list of addresses and for what purpose heaven knows . . . ! The boarding medical officer can hardly explain to all the persons affected the intricacies of the problem he is solving when holding up a good-size village at the point of a fountain pen.

Plan to Combat Infection.

International conventions have arranged measures in connexion with cholera, plague, and yellow fever; as more especially ship-borne, typhus fever and small-pox are added to these diseases for the purposes of port sanitation, and as for other infections, there is an old saw to the effect that "if the kitten cannot get in at the same hole as the cat it can stop outside and mew." A cul-de-sac is therefore arranged for infection on the following plan.

An officer of H.M. Customs questions the master, or surgeon if one be carried, of every ship from a foreign port as to the health of the crew and passengers. The medical officer hears the answers to the questions "Are you all well on board?"; "Have you had any sickness or death during the voyage?" He examines every case of illness declared, and if it is "reasonably necessary" examines the remainder of the ship's complement. Such reasonable necessity is implied for every ship which has come from or touched at a port infected with any of the diseases mentioned above or which may be suspected of them or of rat-plague infection, whether any illness has or has not been declared.

As to the method of examination, the closer the contact of the medical officer with the personnel the more chance he has of covering the whole field comprised in the word infection. Should an officer not feel for buboes in examining for plague he would not find cloaked venereal buboes or be able to account for every bubo on the ship as it is part of his duty to do, while to miss seeing the last man is to miss the one presumably incapable of the effort of mustering. The wrists and face of the examinee under scrutiny give their specific and general indications, as illustrated in small-pox and tuberculosis respectively, and a generally "seedy" expression requires a general examination, for which purpose the possessor is set aside from the muster.

Importance of Examination of Ships.

The satisfactory examination of a ship is obviously the most important and difficult individual operation in port sanitation. Those observers over tens of thousands of years from whom Moses and Solomon cribbed their saws and made useful generalisation had noted that time and tide wait for no man; lately Canute has acquired a spurious reputation from investigating one side of the postulate. Any boarding medical officer on the Thames could add an observation on the co-related impatience of shipping. A condition, once it is found, can be met *secundum artem*, but artfulness as well as acumen is perhaps the more exhibited in the rapid finding.

Port of London Sanitary Authority: New Motor Launch at the Mooring Station.

This examination goes on at the Thames mouth day and night throughout the whole year. A medical officer is always on duty, and no ship from "foreign" goes alongside a wharf or into dock without his visit. He has the privilege of seeing the summer sunrise and of climbing a vertical rope ladder when a rough sea makes companion-way inadvisable and a hasty ascent imperative. He has the tedium of "drawing blank" week after week, as also at intervals the satisfaction of a capture well worth the making and much to the advantage of the public.

It is curiously startling, even to the medical officer himself, how that—not lulled to sleep by a month of even or uneventful tenour—some seemingly casual but really well-directed glance at a face or log-book puts in motion a machinery which has its repercussion from Land's End to John o' Groat's. This apparent casualness in discovery is only the result of long acquaintance with the likely situation of both mare's nest and genuine brood and a rapid orderly method of search which, if satisfactory to the medical officer himself, is usually so to everybody concerned.

By the courtesy of H.M. Customs and an arrangement which has its mutual advantages, the boarding medical officer makes his visit on the Customs launch. His headquarters are on a hulk which externally may suggest to the economist that after all the cheapest thing which is efficient is best; internally it is a comfortable set-off to the chilly blasts of winter. This situation afloat and far away from town is well adapted to readiness for and success of the procedure of examination and disinfection. The hulk *Hygeia* also forms a mooring station and headquarters for two of the three launches of the Port Sanitary Authority, and is in telephonic communication with the inside world by submarine cable.

The turning out of the foc's'le quarters and their complement of, say, 100 in the case of small-pox or plague for disinfection implies launches and capacity. Such disinfection, as also the removal of patients and contacts to the hospital and the disinfection of ship's quarters, is under an inspector, who takes his directions from the boarding medical officer. The inspector is in charge of the launch, and one of his primary sanitary qualifications is that, having been a seaman and a master at one time in his career, he speaks with the officers of the vessel held up, of the bows and bulwarks not of sharp ends with railings, and can sling a patient on a stretcher from a davit with the best; that he knows where the buckets and mops are, or should be, stowed on the ship, and where are the likely rat-runs between holds and deck.

Disinfection on Shipboard.

Disinfection on shipboard includes such diverse organisms as men, rats, fleas, mosquitoes, lice, and bacteria. Efficacy, as usual, depends on the human element; effective application is as necessary as the armamentarium. The close quarters on shipboard demand a thorough disinfection of both place and fomites as well as removal of the chief—i.e. (except in the case of plague), the human—reservoir of infection; all follows on that wide knowledge of ætiology of each of the diseases dealt with which is now available. The place and time for this work is in the river before the ship reaches dock; a clean sweep of the infection on board must at least be arranged before the ship proceeds to wharf or dock. Hence the uses of a launch fit to stand up to a wind-against-tide swell, with capacity for a bunch of natives and their bedding, clothing, and ditty boxes, and ready for action at any time of the day or night.

The new launch of the Authority, named after the present chairman, *Joseph White*, as also her smaller companion, the *James Howell*, fills the book. The name of Messrs. Husk, of Wivenhoe, the builders, is a guarantee for a strong and fitty build. The estuarine conditions and absence of shipworm at the *Hygeia* moorings admit of unsheathed wood instead of steel in the hull. The dimensions are: Beam 15 ft., length 74 ft., gross tonnage 62, draft 4 ft. 6 in. aft, moulded depth 8 ft. Her speed is ten knots with twin Thornycroft 50 h.p. engines, petrol or paraffin. In the absence of any necessity for boiler space comfortable seating capacity in the enlarged cabin space is provided for 40 and standing room for the whole crew of a 6000-ton ship.

When putting away the motor-car after a long day or taking her out at quick notice by night, the practitioner, whatever his love of horse, must be sensible of the time-saving over the necessary unharnessing and bedding-down associated with the horse and gig; much the same is the advantage of motor over steam-engines in this part of the work of the Port of London Sanitary Authority. In the latest launch the Authority has finally changed over from the sizzle of steam to the whirr of internal combustion engines. The work of the Authority is necessarily a somewhat silent one.

ORARGOL

(A.F.D.)

An electrically prepared suspension of colloidal silver and gold for

RHINO-LARYNGOLOGY

AND

OPHTHALMOLOGY,

AND GENERAL ANTISEPSIS.

Indicated in the same diseases as colloidal silver, Orargol has a superior action because of the addition of the powerfully anti-infectious colloidal gold.

"Pharmasol" Nose Spray

A small spray specially made for nasal treatment with colloidal solutions (Orargol, Pharmasol Argentum, etc.).

EASILY STERILISED.

FULL PARTICULARS ON APPLICATION.

Telephone : MUSEUM 4029.

Telegrams : "AMPSALVAS, LONDON."

High Blood Pressure

(Hyperpiesia)

Postulate 1

Let it be granted that the intestine daily contains large quantities of toxic substances from the decomposition of food by bacteria.

Postulate 2

Let it be granted that the absorption of these toxins must result in *diminished resistance*, or loss of control of the natural defences of the tissues generally.

Postulate 3

Let it be granted that these toxins circulating in the blood are conducive to all the symptoms and signs associated with high blood pressure.

Then it can be demonstrated that *treatment for permanent improvement* of persons suffering from high blood pressure must include some form of daily intestinal disinfection to control the manufacture of 'pressor' toxins.

Dimol does this effectively*

It has a bactericidal co-efficient 35 times that of pure phenol.

It is absolutely non-toxic and does not find its way into the circulation.

It can be given over prolonged periods without any deleterious effects on the intestinal mucosa.

** Clinical evidence will be sent to any Medical Practitioner on application to the Sole Distributing Agents—*

THE LANCET.

LONDON: SATURDAY, JUNE 27, 1925.

REFORM OF THE POOR-LAW: THE APPROACHING OPPORTUNITY.

IT is not, we hope, merely fantastic, in the twenty-fifth year of the century, to treat the question of health progress in quarter-century periods. The last quarter of the nineteenth century witnessed that remarkable advance in sanitary science and that tremendous development in environmental hygiene which owed its inspiration to the great reformers of the mid-Victorian era, and which followed upon the recommendations of the Royal Sanitary Commission in 1871. In the succeeding period of 25 years we have seen a quickening of the public conscience in regard to communal suffering and distress which has found its expression in legislative and administrative measures directed to the amelioration of the lot of the individual. Those hard-worked words "overlapping" and "coördination" have been doing good service in recent years and they have a long period of activity in front of them. It is, we suppose, common ground that in the health legislation of the two quarter-century periods to which we have referred there is no clear evidence of proceeding according to plan. Here some new function has been tacked on to the work of an existing authority; there a new authority created and set working on independent lines. Where provision has been made, as in the National Health Insurance Act of 1911, for coöperation with existing bodies, it has been largely a dead letter. And so, on the threshold of another 25-year period, stands Mr. NEVILLE CHAMBERLAIN facing a wonderful opportunity. With the impatience of those who will question the need for the elapse of so long a time before a proper development of the plans of public health are laid down definitely and who would like to put things right to-day, we have much sympathy. But to the discerning observer it is clear that over such a region as there is to travel rapidity of movement is impossible. This third period of 25 years, we venture to say, is to see the plans prepared for statesmanlike structure of public health administration, the foundations laid broad and deep, and maybe the building itself erected, equipped, and fully functioning.

In support of the long view in these matters we may reflect that it was so far away as 1871 that the Royal Sanitary Commission recommended that there should be one local authority for all public health purposes in every place, so that no area should be without an authority or have more than one; It was in 1909 that the Poor-law Commission made those recommendations, to which successive Ministers have given their blessing, for the abolition of boards of guardians, whose functions were referred to by the Maclean Committee in 1917 as involving the largest and the most intractable case of overlapping with other authorities. Mr. NEVILLE CHAMBERLAIN has recently reaffirmed his intention of tackling the problem of the reform of the Poor-law. He would, we expect, be the first to disavow any suggestion that the health functions of the guardians are being inefficiently performed. It is generally recognised that a large and increasing number of our Poor-law infirmaries are in a position to place at the disposal of the poor and destitute members of the community professional care and equipment beyond the reach of a large majority of the members of the community. But the position is that beds in Poor-law infirmaries to the number of 100,000 are, to a large extent, not used to the best advantage or not used at all, while there is a deplorable shortage of beds in our voluntary hospitals. Sentimental objections to the word Poor-law, and recollections of what that word has formerly conveyed, should not blind us to these things. In clearing the ground for the development of a scheme of public health services under one local authority we have in the Poor-law an administering system, levying enormous public funds for the discharge of its functions, which arise from the existence of disease and distress, yet having no duties or powers in respect of their prevention. To say this is to say how much of the old order must be kept, but how much it needs before it can be kept usefully.

We do not detail any instances of overlapping of public medical services, for they are so well known. The Poor-law question in any case is the most serious proposition, and it may be assumed that, in his proposals for the coördination of various public health services which will be discussed with local authorities, including the boards of guardians themselves—and, we have no doubt, the representatives of the medical profession—Mr. NEVILLE CHAMBERLAIN will deal thoroughly and courageously with it. Since the Ministry of Health was created as the first step in the direction of placing all health services under one control, Ministers of Health have come and gone with rapidity. Mr. CHAMBERLAIN has before him, as far as one can foretell, a long period of office. He is, we believe, a man of untiring industry, and if he is approaching in a broad spirit the great and intricate problems, he will have accepted a splendid responsibility for developing a new era of public health administration. The problems, as we have said, do not lend themselves to rapidity of solution. Questions of valuation and of reconstruction of areas necessitate consultation with large groups of interests and with many types of experience, and perhaps the overthrow of groups and individuals who will die hard. The opportunity approaches for big work in a big cause.

◆

THE PURSUIT OF PURE MILK.

MILK is the most important food available to mankind. Every medical practitioner is aware of its value, but his desire to see it more fully utilised is frustrated by his knowledge of the unsatisfactory conditions under which, only too frequently, it is placed upon the market. Few foods have received more consideration, and for few have more strenuous steps been made to obtain a better product. In a series of articles, completed in this issue, Dr. W. G. SAVAGE discusses the problem and why these efforts have not been more successful. One cardinal factor in the position is that the supply of milk is a matter of great importance to the agriculturist, and agricultural interests have often been exerted to frustrate efforts to provide efficient control. The greatest contamination of milk takes place at the cowsheds which are mostly in rural areas, and the control over production is placed and retained in the hands of bodies composed almost entirely of farmers or persons directly in business relationship with farmers and milk producers. The control over meat is not left in the hands of butchers and meat purveyors. The 1922 Milk Act added extensively to the control over purveyors of milk, but avoided touching milk production. It is well known that the powers of supervision over milk production are very inadequate, but it will come as a surprise to many medical men that it is not illegal for a milker with unwashed hands and dirty clothes to milk manure-plastered cows with dirty udders into an open pail in a dusty hay-laden shed, and for that bacteria-laden milk to be sent long distances without any attempts at cooling. Control is also very ineffective as regards the prevention of acute infectious disease spread by milk or the elimination of the danger of the transmission of bovine tuberculosis from cows suffering from that disease.

An important point stressed by Dr. SAVAGE is the close relationship between the quality of milk supplied and the demands of the consumer. At present the average producer obtains the same price for his milk, clean or dirty; why then should he go to the trouble and expense of providing a cleaner milk which is of no commercial value to him and which by law he is not compelled to provide? This fact suggests that one fundamental condition for obtaining a clean pure milk-supply is to create a demand for it on the part of the consumer. Clean pure milk must be made a business proposition, and Dr. SAVAGE indicates ways in which this can be done. Incidentally he points out that the medical profession is not pulling its full weight in this matter, both by failing to support actively milk producers and distributors who do supply clean milk, and by neglecting to use influence to see that hospitals and other institutions, in their contracts for milk, specify milk of high bacterial purity. An educated public opinion on this subject will make it much easier to ensure that supervision over milk production and distribution will be effective; the present control is farcical. The existing system of certain special grades of milk is admirable from this point of view as an educative influence, since their existence brings home to the consumer that milk is not a uniform article, one and indivisible, but is of very varying quality and purity. Apart from its educative effect, these grades touch but the fringe of the problem, and it is not very likely that they will extend to more than a small minority of producers. But the risk of the acquisition of tuberculosis from milk is a very real one; and a factor which is the cause of over 3000 deaths a year, on a very conservative estimate, and of a serious mass of preventable disease calls aloud for remedy. Dr. SAVAGE gives no short cut in regard to the difficult problem of the prevention of bovine tuberculosis, and does not discuss the subject in detail. Experience elsewhere shows, however, that it is possible to build up and maintain herds of non-tuberculous cows, while the elimination of cows actively disseminating the bacilli is a valuable auxiliary procedure. The development of orthopædic schemes for treating tuberculous and other cripples will probably give a considerable stimulus to the prevention of bovine tuberculosis, as it will become increasingly recognised that it is folly to spend huge sums on the treatment of tuberculous cripples without at the same time actively taking steps to prevent their manufacture.

We would direct attention to Dr. SAVAGE'S remarks on pasteurisation, since there is so much confused thinking on the subject. The basal fact is that at the present time the bulk of the milk consumed in the large towns is pasteurised by processes which are uncontrolled as regards the temperatures reached or the time the milk is held at a high temperature, and that such milk is sold as fresh milk. Some of it is pasteurised more than once. Reliable data are lacking to enable an opinion to be given as to whether such uncontrolled pasteurisation does or does not damage the nutritive qualities of the milk. It is a trade practice to enable initially dirty milk to survive as a commercial product. Such treatment is entirely different from controlled pasteurisation and distinct from the question whether the latter is in itself a valuable and satisfactory solution of the milk problem. In either case it is a substitution of heat treatment for clean production. A point of interest is as to whether conditions are improving. Dr. SAVAGE, from his unrivalled experience, considers that material improvements have taken place in the handling of milk after production, but that up to two or three years ago there was little evidence of betterment in the bacterial contamination at the cowsheds. During the last few years definite progress has been made, especially in regard to the sowing of the seeds of dissatisfaction with existing methods in the minds both of the producers and of the consumers, and in the better goodwill and understanding of the problem shown all round. The Milk and Dairies (Consolidation) Act, 1915, has never been put in force, but is due to come into operation on Sept. 1st next, and the Minister of Health has stated that its operation will not be further postponed.[1] Much of its value will depend upon the regulations made by the Ministry of Health under Section 1 of the Act, and these have to be framed with the concurrence of the Board of Agriculture. The Act has many defects, but, if efficient regulations are allowed to be made, it should improve markedly the legal control over milk production and distribution. For its efficient working it will need the support of all those who care for clean food. The medical profession believes in clean milk, and considers the consumption of it per head to be deplorably low. It will give its support to any reasonable measures to give us a pure clean milk-supply, and to remove what remains at present a serious blot upon the administration of public health in this country.

◆

PROPHYLACTIC VACCINATION AGAINST TUBERCULOSIS.

VACCINATION against tuberculosis shows signs of revival in a new form. Since the early days of the tuberculin era vaccines in one form or another have never entirely failed to excite interest and experiment in one quarter or another, and it would probably be no exaggeration to say that more time and effort has been spent on the tuberculosis vaccine than on any other form of bacteriological research. Recent years have seen a further application of these researches in one particular direction—viz., the prophylactic vaccine. Old and new tuberculin have both been used in this way for many years, but the efforts put forth have been, on the whole, sporadic and the results equivocal. Shortly after the war popular excitement was aroused in Spain—it seems the fate of tuberculosis remedies to create unbalanced optimism—by the production of the Ferran vaccine. This vaccine was not derived from the tubercle bacillus itself, but from an organism of the *B. coli* group, from which it was claimed *B. tuberculosis* was descended. Dr. J. CHABÁS, in a recent number of the *Revista de Hygiene y de Tuberculosis* (Valencia) has revived this subject, whilst attention has also been called to it in South America.

---

[1] Under Section 14 of the Milk and Dairies (Amendment) Act, 1922, the Scottish Board of Health have just issued an Order, under which the Milk and Dairies (Scotland) Act, 1914, will also come into operation on Sept. 1st, 1925.

In all these writings the main plank in the anti-tuberculosis campaign is held to be the immunisation of the people—especially the infant population—with a specific prophylactic vaccine. Opinion naturally differs almost as widely as do the claims of the inventors as to the value of this or that vaccine. Doubtless the proposition is a fascinating one to all sociologists. The future is in the hands of the children, and if the world can be made safe for the coming generation by protection against such diseases as tuberculosis we have advanced one long stage on the road towards a happy future.

Wide publicity has been given during the past week to the announcement, made in another column by our Paris correspondent, that Dr. A. Calmette and six colleagues have reported to the Academy of Medicine in Paris the preliminary results of prophylactic vaccination against tuberculosis made in two series of cases of infants under one year of age. The basis of Dr. Calmette's work is to be found in researches made by him, over a long period of years, on a culture-medium containing ox-gall, by the use of which non-virulent strains of bacilli capable of producing antibodies in laboratory animals have been obtained. The ape and the calf have also been found to resist infection with this strain. There are, of course, not a few of such strains in experimental use in various laboratories of different countries, and some of them, at least, on careful investigation have proved to be avian strains of the tubercle bacillus of very low virulence. (In passing we may note that a very interesting and illuminating article on these strains has recently been written by Dr. A. Stanley Griffith in the June number of *Tubercle.*) The Calmette vaccine is administered by the mouth in a spoonful of milk every 48 hours from the third to the tenth day after birth. The author states that this method is without danger and "its efficacy is beyond all doubt." Two series of cases have been published. The first is a series of 178 infants treated in 1922. A certain number of these cases appear not to have been traced, but it is stated that 94 are known to be quite well and that no deaths from tuberculosis are known to have occurred. The second series consists of 137 infants treated during 1924. These were all from families in which tuberculosis was known to have occurred. The mortality amongst Paris infants born in such an environment is stated to be 32 per cent. if left untreated, while in the series of 137 cases treated there have been, so far, no deaths. These statistics are remarkable and we await further details with much interest. Do the reports, for instance, state whether or not these last children were left in their tuberculous environment and whether this immunity can be attributed to any other precautions of the antituberculosis campaign, notably removal from the infected homes as is done in France under the famous Grancher system? We ask because a mortality of 32 per cent. among untreated children strikes us as remarkably high, and we do not know on what grounds this figure is suggested.

In conclusion, this experiment in prophylaxis against tuberculosis in infants raises questions which are of fundamental importance to our present views on the wholesale immunisation of a people. In all these large-scale experiments at least two essential desiderata are required. In the first place the bacteriological details of the vaccine must be firmly established, and in view of the doubts cast upon so many of these non-virulent strains of tubercle bacilli we must be quite sure that the strain is a human one. Dr. Griffith's work has shown that this point is by no means a purely theoretical one. Prophylactic vaccine with avian strains might well fail in its purpose. In the second place the sociological conditions for the experiment must be made non-variable as far as possible. Untreated and treated groups of infants must be under the same hygienic conditions, with the same welfare organisation details. Only by so stabilising the bacteriological and sociological conditions can any such experiments be really crucial. These difficulties have been emphasised at some length, as the question of prophylaxis against infective disease is notoriously hard to answer. We have only to follow the discussion which has been going on for some weeks in the *Times* on small-pox prophylaxis to realise how far we are yet from attaining a sociological crucial experiment free from all manner of variable factors.

◆

PATHOLOGY AT CAMBRIDGE.

In the class lists of the Natural Sciences Tripos issued in Cambridge on June 19th the names of four men and two women appear as having taken Part II. in pathology. It is no new thing that pathology should be theoretically, and occasionally in practice, available as a science subject as well as an item in the medical curriculum. But it is a departure full of significance of progress already made, and full of hope for more progress to come, that the subject should reach the position it deserves as a discipline worthy of independent study in one of our ancient universities, where it can be pursued along these lines to such exceptional advantage. The School of Physiology at Cambridge was an infant in the arms of Michael Foster not so many years ago; it has risen to a position which is nowhere surpassed and in few places rivalled, and in its academic devotion to the progress of knowledge has made contributions to practical medicine of the most real and solid kind. We hope that with its new position in the curriculum and its new buildings which are imminent, Prof. H. R. Dean will see the School of Pathology grow and progress to the same distinguished position; medicine is sometimes best served by those who do not go to the bedside.

WIRELESS INJURY TO HEALTH.

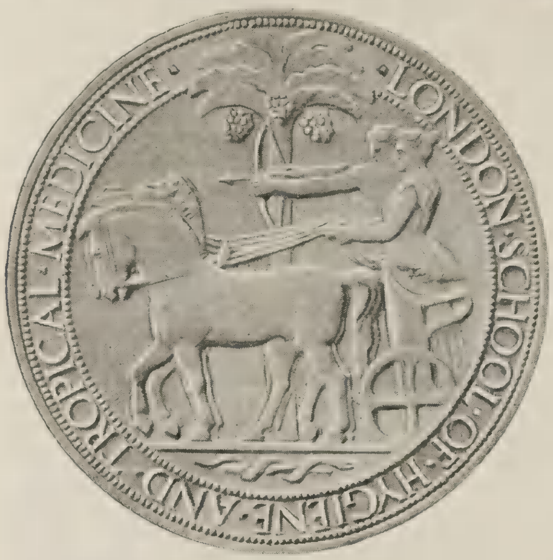
In the early days of the application of the Hertzian waves a close look-out was naturally kept to see if they had any harmful influence on the operators, and in 1909 Dr. P. Bellile, a French naval surgeon on board a vessel engaged in the Morocco campaign, found that a number of wireless operators developed eczema along with conjunctivitis and even keratitis, presumed to be the result of exposure to electric currents. One man complained of painful palpitation, and Dr. Bellile was disposed to think that neurasthenia, then becoming rather common among naval men, might be due to their work in wireless telegraphy. During the 16 years which have since elapsed, in which every large ship and almost every up-to-date household has installed wireless transmitters or receivers, little or nothing further has been heard of injury to health. A recent tragic occurrence in which a wireless operator was electrocuted in the air was shown to have been due to a leakage of current from the magneto. The report just received from New Jersey of the death of six women in a wireless testing department from nervous collapse followed by fever and unconsciousness will not therefore be debited to the action of long wave currents until exact information is received. Happily it seems that the human body has no apparatus able to respond to very long electric waves.

Annotations.

"Ne quid nimis."

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

The munificent Rockefeller gift of $2,000,000 does not come to full fruition until the London School of Hygiene and Tropical Medicine is both built and equipped. This will not be for another two years or so, although the decision will shortly be taken regarding the five excellent series of competitive plans submitted to the Advisory Committee. With characteristic generosity the Rockefeller Foundation, however, has guaranteed the sterling value of the gift as from the date when the offer was made. The undertaking of the British Treasury to provide funds for the upkeep of the school also does not come into force until the fabric is complete. In the meantime, however, thanks to an interim grant from the Foundation, the new directorate has taken over the London School of Tropical Medicine and Dr. Andrew Balfour has been busy remodelling the curriculum as far as ways and means permit.



The diploma course in tropical medicine has been extended by the addition of lectures on biochemistry, by giving much more attention to tropical hygiene and by the introduction of tutorial weeks. Two courses of study, each lasting five months, now occupy the academic year; one course begins in October and terminates in February, the other in March terminating in July. More clinical demonstrations will be given in the wards and opportunity offered for the study of minor forms of tropical disease at the Albert Dock Hospital and on ships adjacent thereto. Research is to be put in the forefront of the programme and a number of studentships have been instituted, carrying an income of £250 per annum. Holders of these research studentships will give help as demonstrators in the diploma courses, but will have a large part of their time free for independent research. The demand at present for skilled workers in protozoology and entomology by Colonial Governments is greater than the supply. That these Governments are themselves awakening to the value of research was indicated in recent replies (summarised on p. 1381) by Mr. Amery in the House of Commons, although the proportion of expenditure on this head to the total cost of medical and sanitary services is as yet conspicuously small.

The London School is now proposing to utilise overseas laboratories on a concerted basis rather than to continue the policy of research by expedition, as has been the practice in the past. Within the last few days a proposal has been made to develop the Natural History Museum at Nairobi into a centre for tropical research as a memorial to the late Sir Robert Coryndon, and a Rockefeller gift of £44,000 to the Singapore College of Medicine has been announced for the endowment of chairs of bacteriology and biochemistry. The aims of the London School are typified in its new seal, of which an impression is here given. The design, executed by Mr. Allan Wyon, owes its inspiration to a coin of ancient Sicily, where with little doubt the allusion is to the deliverance of the city of Selinus from a pestilence caused by the stagnation of the waters of the river. Apollo and Artemis are proceeding slowly in their chariot, Artemis driving while her brother, the sun-god, discharges arrows from his bow. The arrows are the healing rays of the sun, which drive away the malaria mists; and Artemis is beside him as the goddess who eases the pains of women labouring with child. The palm tree and the snake have been added to the Sicilian design.

The arrangements here described concern the teaching of tropical medicine for its special diploma, rather than the more general work on public health teaching which will be taken over by the school when completed. The requirements of public health students are being met in London at present at University College, King's College, Middlesex Hospital Medical School, and the Royal Institute of Public Health, with a special course on sanitary law and administration at St. Bartholomew's Hospital Medical School. It is proposed to develop the teaching of applied physics, physiology, and principles of hygiene, for which at present facilities simply do not exist, and public health students will also attend a course in parasitology to be given at 23, Endsleigh-gardens by Colonel A. Alcock, Prof. R. T. Leiper, and Dr. J. G. Thomson. At the same time opportunity will be taken of collecting a graphic museum of public health, something on the lines of the Ministry of Health exhibit now showing at Wembley, which will not be allowed to be disbanded when the Exhibition closes.

DETERMINATION OF SEX.

We had occasion recently to point out [1] that the association of male and female with the right and left sides of the body respectively is a general belief in some form or other among all nations and peoples. Mrs. Monteith Erskine's book,[2] which we had not then received, confirms this statement. Mrs. Erskine now writes:—

> "The theory which I have set forth and elaborated in my book 'Sex at Choice' is no untried recruit to the domain of biological hypothesis, but a hardy veteran who has stood the fire of 25 years' intensive practice and constant operation. It is in the workings of the left ovary as distinct from the right, and in the contention that both boys and girls may be conceived in the same month, leaving the alternate one completely fruitless, that the essence of my theory consists. For its substantiation I have utilised to the full the personal opportunities afforded by my own sex and maternity, probing to their depths the mysteries of pregnancy in its every phase. Furthermore, by sifting the researches of many medical and lay friends, by exhausting the contents of nearly every treatise of sex-determination from Hippocrates downward, by penetrating into the homes and confidence of women of every class of society, and finally by gathering from thousands of cases, where my formula was used, an accumulation of data undisturbed *by any vestige of contrary evidence*, I have secured the assurance necessary to lay my theory before the bar of public opinion. It is for time alone to pronounce judgment."

We have no desire to deny the possible truth of the views set forth by the late Dr. Rumley Dawson or of those now advanced by Mrs. Erskine. It is a priori likely that a belief so universal as that which connects the sexes with the sides of the body should have some sort of foundation. But that is quite a different thing from accepting such views as true. There is, so far as we know, no proof at all of the existence of the biological condition which seems to be assumed by both these writers. The different functions of the two sets of organs, on the other hand, constitute a conception which does not seem to fit in with such facts as the mixed nature of the sexes in the two uterine tubes in animals with large litters, or the presence only of one-sided organs normally in certain orders of animals. This last, by the way, may be associated in some way with the reversed idiochromosome arrangement to which Mrs. Erskine also refers in her letter. Chromosome observations, tentative as they now are, must be taken into account as future factors in deciding these questions. Their inherent difficulty has delayed progress, but if they materialise as they promise to do, they will form a body of positive facts that cannot be denied. Nevertheless, we must not lose sight of older experimental work, which showed that environment has some influence on sex-production in invertebrates and amphibians, and possibly a parallel may be admitted in the changing of sex after birth, which is known to occur even as high in the zoological scale as the birds. It may be objected quite properly that the human subject may have specialised in this matter on different lines, but it is clear that the chromosome factor and the environment influence do not necessarily stand as opposed hypotheses. At present it is enough to say that *if* and *when* the chromosome factor is established it will apparently be one with which all other views must be congruent. The clinical observations of Dr. Dawson and Mrs. Erskine may turn out to be approximately correct so far as conclusions drawn from them are concerned, and in the absence of crucial experiments they command attention; but they must give way to such evidence when it is forthcoming. We do not wish to lay any stress on the various anatomical and physiological crudities occurring in the book—these are only to be expected and do not affect the issue—but it must be pointed out that the one essential point is the demonstration of qualitative difference between the ovaries, and this is at present totally lacking.

SUNLIGHT AND CANCER.

EXPERIENCE has taught us that almost all our therapeutic agents are double-edged weapons and must be used with care and moderation if the evil that they do is not to live after them. The virtues of the solar rays in the prevention and cure of disease have been so loudly acclaimed of late that their rôle in its causation has received hardly any notice. In this country the question is not acute and in those regions where the sun has great power Nature has endowed the natives with protective dermal pigment, and the dangers of acute sunstroke are so vivid that the northern visitor takes elaborate precautions against exposure. It is only in the middle zone, where the rapid acute effects do not occur and the blonde, with his inadequate protection of freckles, works day by day in the sunlight, that we can expect to see the chronic lesions brought about by solar rays. Prof. W. Dubreuilh, of Bordeaux, in delivering the annual oration before the London Dermatological Society on June 17th, adduced much evidence to prove that the cumulative effect of prolonged exposure to the violet and ultra-violet rays in sunlight is responsible for those changes in the skin which are commonly, but erroneously, ascribed to senility. The only true senile change is loss of elasticity; the macular discoloration, the patches of small distended vessels, the white achromic macules, and the crusty or scaly areas are all pathological and constitute an ensemble described by Prof. Debreuilh in 1908 as "keratosis senilis." This term he would now make interchangeable with "keratosis solaris." The condition occurs only on parts exposed to the sun, and its connexion with exposure is well seen in the elderly peasant women who have worked in the fields all their lives, their heads protected by the conventional folded kerchief. Beneath the kerchief there is no "senile" change save wrinkling; the uncovered part of the forehead and ears, the face and the hands show all the characters of keratosis senilis. The condition is to be grouped with leuco-keratosis of the tongue, arsenical keratosis and Paget's disease of the nipple. It passes imperceptibly into that described by Prof. Debreuilh in 1896 as "precancerous keratosis," and epitheliomatous cells can be recognised histologically long before there is clinical evidence of epithelioma. The malignancy is no accidental supervention, but the final and inevitable stage of the process, if it be continued over a long period, even if the stimulus has ceased to be active some time previously. The distribution of epitheliomata supports the theory of solar origin. The terminal phalanges are very rarely affected, since these are wrapped round the hoe or other implement and so are not exposed. A striking contrast is seen in the X ray cancer, where these parts are as commonly affected as the rest of the hand. The dermoid is apt to occur at the inner canthus of the eye, the epithelioma scarcely ever, since that area is the part of the face most protected from direct sunlight. The preponderance of these epitheliomata of face and hands that come from country districts has been noticed by Bellini in Milan and by McCoy in America, as well as by Prof. Debreuilh in Southern France. McCoy has even noted that the condition is more common where there is a chalky soil, which reflects and enhances the effect of the direct ray, perhaps also increasing the relative proportion of the shorter rays. Southerners are rarely affected, Arabs and such dark-skinned races never, and the incidence falls far more heavily on the blonde than on the brunette. German observers have described a carcinoma of seamen, a phenomenon occupying a position intermediate between keratosis solaris and xeroderma pigmentosa. Here again the reflection of the rays from the surface of the sea is to be regarded as the reason for its limitation to seafarers. Prof. Debreuilh's observations of the rare xeroderma pigmentosa have led him to regard it as an acute form of keratosis solaris occurring in early childhood, as soon as exposure begins, owing to a peculiar sensitiveness of the individual skin. The length of the radiant wave seems to affect the nature of the lesion. The calorific rays produce instantaneous effects, with very rapid necrosis and much pain. Examples of their more chronic effects are the condition met with on the shins of those who sit much over fires during the winter, the epitheliomata of the shins of stokers, and the Kangri cancer, but these are late and rare developments. The X rays produce a slowly developing and slowly fading erythema. Numerous short exposures result in a cumulative effect similar to that of sunburn. The lesions of the violet and ultra-violet rays have a latent period of many hours and never show much necrosis. The grave results are only seen after years have passed. The latent period for the Rontgen rays is much longer—10 or 15 days—and the pain is less; the chronic effects appear sooner and are more serious.

COHNHEIM'S EXPERIMENT ON INFLAMMATION.

Two different views are held concerning the origin of the cells seen in the early stages of inflammation in the inflammatory exudate. Cohnheim taught that they are exclusively leucocytes which had emigrated from the blood-stream, a view which has been accepted, though not in its entirety, by the majority of pathologists. On the other hand, there are such distinguished authorities as Virchow, Stricker, and Grawitz who maintain that these cells are derived almost exclusively by proliferation from the connective-tissue elements and that emigration from the blood-vessels plays only an inconspicuous part. The problem has been the centre of a prolonged and extensive controversy during more than 50 years.

U. Westphal[1] has recently repeated Cohnheim's original inflammation experiment in order to obtain fresh evidence. By direct microscopic observation of the frog's mesentery he could follow all the stages of diapedesis of leucocytes from the blood-stream through the walls of the capillaries. This could be rendered particularly clear by a preliminary injection of neutral red. The leucocytes engulfed the red granules of the dye, and being thus coloured their paths could be followed readily. In another series of experiments the mesenteries were fixed after varying periods and the oxydase reaction applied to the various pieces. It is claimed that this reaction, in which indophenol-blue is formed owing to the presence of an oxydase in the cells, is almost specific for the polymorphonuclear and the eosinophile leucocytes, and is not given either by lymphocytes or the cells normally present in connective tissue. It was found that the normal mesentery shows only a few isolated cells in the capillaries giving this reaction, while the inflamed mesentery shows an accumulation of these leucocytes, stained a deep blue, at first within the capillaries and later as the inflammation proceeds in the connective tissue outside the blood-vessels. Westphal concludes therefore that in the early stages of inflammation—i.e., the first 24 hours—there is a massive emigration from the blood-stream of the polymorphonuclear leucocytes into the connective tissue and that these represent the bulk of the cells of the inflammatory exudate during that period. A very interesting result was obtained when a leucopenia had been produced by the injection of benzene. Blood films showed that though the leucocytes were greatly diminished they were not completely absent. But no leucocytes at all were seen in the inflammed mesentery of such animals even after 24 hours. This result indicates that diapedesis is not merely based on mechanical factors, such as pressure, but is a manifestation of the activity of the living leucocytes responding to stimuli such as chemotaxis. When the vital activities of the leucocytes are impaired, as they were in this experiment by the toxic action of benzol, this phenomenon of diapedesis fails to appear. The technique of the experiments is described in detail and the results are illustrated by instructive microphotographs. It would seem very suitable as a class experiment in a course of experimental pathology.

A WELL-EQUIPPED PASSENGER SHIP.

THE *Crested Eagle* is a new ship of the General Steam Navigation Company which is to run daily, Fridays excepted, from London Bridge to Margate and Ramsgate, starting at 9.30 A.M. and arriving back about 8 P.M. Our representative, experienced in ships, who was invited to view her, came back frankly charmed. The *Crested Eagle* was built by White, of Cowes, paddle-wheeled, but with the flared-out bow of a destroyer to keep her forepart dry even when travelling at her usual 18½ knots. She is planned to carry 1791 passengers, all of one class, and is accordingly designed with everywhere large gangways, wide doors and staircases, and unusually unobstructed decks. She burns oil for steam-raising, so there are no ashes to make the decks gritty, and she is exceptionally well ventilated. The promenade deck, the highest, is one level plane from bow to stern, and on it are hundreds of seats, buoyant, life-saving, for passengers. The upper deck, on which one arrives, is less spacious, but its level is only interrupted by a very small rise over the paddle shaft. On this deck is the great pride of the owners, the restaurant, forward, lighted from the sides by windows, which can be shuttered in bad weather at sea, but, open as they will be in the river, they allow the 120 diners at thwartship (cross) tables, to get, every one of them, a view outboard of the river and its traffic, all the time of the meal, just the view obtained out of a Pullman car but unusual in a ship. There are half-a-dozen forced draught supplies from a trunk each side, and two 6-inch shafts amidships as exhausts. Below this is the grill-room for 40 guests (a silver grill in the galley—i.e., kitchen), with a fresh-air supply down the centre of each table and an exhaust forward. Aft on the upper deck is the main saloon, with heavy carpets and good upholstery, vacuum cleaned every morning; aft of this is the ladies' room, quite comfortable, with lavatory basins, and four well-ventilated, well-lighted, roomy w.c.'s. Off the midship end of this saloon there are, on the port side, a stair to the smoking-room and bar, and starboard, another stair to the tea-room, comfortably fitted and well ventilated. Amidships are the w.c.'s, urinals, and lavatories for passengers, white painted and well lighted throughout; quite satisfactory. The bars, kitchen, and pantries are all well lighted and well ventilated. It is pleasant to see so much consideration given to the comfort of the staff. A word must be said of the ventilation discharge outlets; they are round like oranges, and set in a spherical bearing, within which they move quite easily. Consequently, the air discharge, through what one might consider the polar circle of the orange, can be readily directed to the floor or the ceiling, or directly on to oneself if desired. With this outlet no ventilating current can be so easily prevented from becoming a nuisance. As the ship carries some 45 tons of drinking water, taken in from London daily, it has been possible to install a soda fountain, and all refreshments, solid and liquid, are kept well cooled, there being a large refrigerator on board by Halls, of Dartford. It may be mentioned that, above the promenade deck, is a large cylinder, a fire extinguisher, half containing acid, half an alkaline solution. In case of a fire these would be discharged upon it together, when it is expected that that fire would be at once smothered by the carbonic acid. Life-belts are carried under each saloon seat. The crew's fo'c'sle is aft of the collision bulkhead forward, and has 12 beds, with spring bottoms and mattresses, away from the ship's side; a rough eye measurement suggests there are 150 cubic feet for each man, and there are sprays, lavatories, and w.c.'s for sailors and stewards, just as good as for passengers. This is as it should be. The summer trips of this ship should be cool and pleasant.

GOING WEST.

ESCHATOLOGY is always a fascinating study and beliefs as to conditions after the death of the body are distributed throughout the world, but these beliefs are, from the limitations of our present mental powers, of necessity either hypothetical or inspired by faith. Those persons who are mentioned in the Scriptures as having returned from the dead have left no record of their experiences in the next world, and the descriptions of that world left us by the great classical writers, Homer and Virgil, by Cicero in the Somnium Scipionis, by Plato in the vision of Er as given in Book X. of The Republic, and in Dante's Divine Comedy are, so far as we know, flights of intellectual imagination. Nevertheless, belief in a future life is in some form or another a universal belief, and there exist such similarities between the beliefs of different nations and peoples as to make it probable that they are all variants of one primitive creed. Perhaps the most universal belief concerning the next world is that it is reached by a journey which includes the crossing of the sea or of a river by the soul. Miss Rosalind Moss[1] has no doubt that "in many places the belief in an afterworld across the sea is due to migration, the souls of deceased immigrants returning to a home of the dead in the land from which they came." This land, as a rule, lies in the west, because from that region the original inhabitants of Polynesia came. It seems to us, however, that the migration theory will not explain the universal folk-lore belief in Europe that the land of the dead lies to the west. The euphemism "go west" for "die" has passed into a proverb, among the Celto-Iberian peoples the land of the dead lies to the west, the Vikings laid their dead in a ship on a pyre which was fired and then the ship sent out to sea, the Fortunate Isles and the Isle of St. Brandan were all in the west and so were the Hesperides; the westernmost point of Brittany is full of traditions of a race whose profession was rowing the souls of the dead across the sea. According to Procopius, the land of the dead was Brittia—i.e., England, which, together with Ireland, was the westernmost portion of Europe. Finally, we have the traditional land of Atlantis. Now the migration theory does not explain these beliefs, unless the inhabitants of Europe originally came from Atlantis, and it seems to us more likely that the idea of the land of the dead being situated in the west arose from the sight of the daily apparent course of the sun.

---

[1] Eine Nachprüfung des Cohnheim'schen Entzündungsversuchs, Frankfurter Zeitschr. f. Pathologie, xxx., 1.

[1] The Life After Death in Oceania and the Malay Archipelago. By Rosalind Moss, B.Sc. Oxon. London: Oxford University Press; Humphrey Milford. 1925. Pp. 247. 14s.

Miss Moss tells us in her preface that the purpose of her present inquiry is to trace the connexion between burial customs and beliefs in a future life among the more primitive peoples of Polynesia, Melanesia, and Indonesia. She has collected an enormous amount of information as to burial beliefs in Polynesia and the journey of the soul after death, and everywhere we find the same ideas as are current in Europe. The ordeals and tests which the soul has to pass are much the same as those described in that curious folk ballad, "A Lyke-Wake Dirge," which mentions the bridge which must be crossed. Again, the dead do not depart at once for the spirit-world but linger for some days round the body. This belief is not extinct even now in Europe; not many years ago a medical man told us that a patient of his had left a request that his body should be cremated. The mother of the dead man absolutely refused her consent. When asked why, she said that if the body was burned the soul of the dead would at once depart and not linger round the grave. The persons concerned were of high intellectual capacity. Miss Moss's book is well worth reading, her material is well put together, and she does not dogmatise; but all the beliefs which she has collected go to show that humanity has preserved a deep-lying stratum of creed which must have come down from the long ago when the human race was one people.

INTERNATIONAL CONGRESS OF RADIOLOGY.

The International Congress of Radiology which, as we have already announced, will be held in London from July 1st to 4th, may certainly be regarded as an important node in this rapidly growing branch of medicine, for in its size and scope it will be greater than any such assembly hitherto held. The Congress is the direct outcome of one of the first proposals made by the British Institute of Radiology on its foundation some two years ago, and the number of foreign countries represented on the conference programme forms a very striking proof of the high value that is set on the international discussion of the many problems with which radiology is now faced. In this connexion we might draw attention to the letter on p. 1370 of this issue, setting forth a scheme proposed in Vienna for an international association of teachers of medical radiology. The United States of America, France, Germany, Austria, Belgium, Norway, Sweden, Denmark, Italy, Czecho-Slovakia, Switzerland, and Russia are among the countries represented at the Congress, and well represented. The meetings will be held in the Central Hall, Westminster, where an exhibition of apparatus will also be on view. The Congress will be officially opened on July 1st at 2.30 P.M. by the Duke of Connaught, accompanied by the Minister of Health (Mr. Neville Chamberlain). On the previous evening, June 30th, a preliminary reception will be held by the President of the Congress, Mr. Thurstan Holland, at the house of the Royal Society of Medicine, 1, Wimpole-street, W. The official Congress dinner will take place on the evening of Thursday, July 2nd, in the Great Central Hotel. The work of the Congress will be divided into three sections: Physics, electrotherapy and actinotherapy, and radiology respectively. On the morning of Wednesday, July 1st, Sir William Bragg and Dr. Béclère, of Paris, will open an important joint discussion between the sections of physics and of radiology on international units and standards for X ray work. In the evening the Sylvanus Thompson Memorial Lecture will be given by the Duc de Broglie on Absorption of X and Y Radiations and the Secondary Radiations which Accompany Them. On Thursday morning, July 2nd, various papers will be read in all three sections. Discussions on electrotherapy and actinotherapy will be opened by Dr. E. P. Cumberbatch and Sir Henry Gauvain respectively. In the afternoon the physics section will visit the National Physical Laboratory at Teddington. On Friday, July 3rd, discussions in the sections of physics and actinotherapy will be continued, while in the radiology section papers will be read on the thoracic organs and X ray therapy. In the evening the Mackenzie Davidson Memorial Lecture on the relationship of radiology and surgery will be delivered by Sir Berkeley Moynihan. On Saturday morning, July 4th, papers will be read on the diagnosis of diseases of the nervous system and on X ray therapy, and at 12.15 P.M. a meeting of the international delegates will be held to consider the formation of an international committee. The office-bearers of the Congress are as follows:—President: Mr. Thurstan Holland. Vice-Presidents: Dr. A. E. Barclay (President of the Rontgen Society), Dr. Stanley Melville (President of the Electro-therapeutics Section of the Royal Society of Medicine), and Sir Humphry Rolleston (President of the British Institute of Radiology). General Secretary: Dr. Stanley Melville. The joint executive secretaries are Drs. J. E. A. Lyndham and J. Muir, from whom copies of the programme and other information may be obtained at 32, Welbeck-street, London, W. 1.

ACTION OF WATER ON COPPER SERVICE PIPES.

A few months ago we directed attention to a pamphlet which was being widely distributed by the Copper and Brass Extended Uses Council advocating the use of copper for service pipes for water distribution, and we then remarked that little was known about the action of various types of water upon copper, and that before the general use of this metal could be advocated the subject seemed to require investigation. A second edition of the pamphlet has now been issued quoting freely results obtained by Dr. J. C. Thresh with various waters, which were the subject of a special article in The Lancet of March 28th last. It was shown in this article that practically all waters—acid, neutral, or alkaline—act upon copper, the reaction taking place between the oxygen in solution and the metal, a hydrated cupric oxide probably being formed which is very slightly soluble in acid-free water. If a trace of copper as sulphate is added to pure distilled water and the solution is then rendered alkaline by the addition of a trace of potassium hydrate the liquid remains clear and bright and the copper therein can be easily estimated. If the liquid, however, is filtered through paper most of the copper is removed, and if filtered through asbestos or a Pasteur filter, the whole of the copper disappears. Hence the hydrate formed probably exists in a colloidal condition. If the alkaline hydrate solution is acidified with carbonic acid, filtration produces the same effect as with the alkaline water, but if acidified with the merest trace of acetic or other acid, filtration removes none of the copper. These facts explain the action of natural waters. If the water contains no free acid save carbonic the amount of copper taken up is exceedingly small, varying from 0 to 0·1 per 100,000, but in the presence of any stronger acid, as in many moorland waters, the quantity taken up may even exceed 0·5 per 100,000, its amount depending upon the free acid present. With such acid waters copper dissolves in amounts which may be dangerous to health, and in time also the life of thin copper pipes may be affected. Copper pipes of suitable thickness for non-acid waters are now cheaper than lead pipes of corresponding strength, a point which is dwelt upon in the pamphlet, but it is obvious that however slight the action of the water on the metal there will be a tendency in time to reduce the thickness and the pressure resistance of the pipes. It is, however, argued that the natural tendency of the action of a water on copper piping is to form a microscopical film and thus to slow down. Laboratory experiments confirm this alleged tendency for the rate of action to decrease, but not with all classes of water.

The Ministry of Health in their Model Specification for Copper Pipes recommended pipes a little stronger than those suggested by the Council, and until such pipes have had an extended trial the Ministry's proposals would be the safer to accept. In any case it is certain that copper is much less readily oxidised and much less dangerous to health than lead. Copper so far as we are aware is not cumulative in the system. Dr. Thresh came to the conclusion that if any water did not take up more than one-tenth of a grain of the metal after being in contact therewith for 24 hours there would be no danger to health. In actual use water would rarely stand in contact with the metal pipes for more than eight to ten hours, hence it would not take up this quantity. In all cases water which has stood for the night in any metal pipe should be run to waste in the morning. The water which afterwards passes will thus have been in contact with the metal for a much shorter time and will contain very little if any copper in solution or suspension. The remarks on tin-coated lead pipes are worth noting. Common tin coatings, alloyed with lead, it is stated, are as dangerous as lead itself. Copper with a coating of 50-50 tin and lead was found to surrender as dangerous an amount of lead to a plumbo-solvent water as did lead itself. Unless, therefore, pure tin coating is insisted upon and supplied, tinning is a snare. In the experiments quoted, copper of a high degree of purity was used and the results only apply to pipes made of such metal; the copper used in water services should therefore comply with the specification quoted in the pamphlet.

We are not concerned with the many other advantages claimed by the Copper and Brass Extended Use Council as the result of the substitution of copper for lead or iron. The report has been compiled with such care that the conclusions are likely to inspire confidence.

THE ASSESSMENT OF IMPROVEMENT IN HEARING.

Medicine suffers under the disability that it is not an exact science; in statistics referring to the results of any form of treatment we frequently have to be content with such expressions as "better" or "worse," "improved," and "in statu quo," and we seldom have an exact scale by which to measure the degree of improvement or its opposite. But occasionally an opportunity occurs for making more accurate measurements of results. In The Lancet for May 2nd there appeared a description by Mr. C. M. R. Balbi of the audiometer, an electrical instrument designed to produce sounds of a frequency ranging through the length of the audible scale, the amplitude of which can be varied in intensity and accurately measured. With an intelligent subject the limits of audition for a tone of any frequency can be measured and plotted on a chart. In our next issue, that for May 9th, Mr. George C. Cathcart described the results of his treatment of chronic progressive deafness by the electrophonoide, an instrument, also electrical, which produces sounds of any required pitch and intensity, and which appears to give beneficial results by causing vibration of the tympanic membrane, vaso-dilatation of the vessels, and stimulation of the nerve-endings in the organ of Corti. Mr. Cathcart made the definite statement that of 100 cases of chronic progressive deafness, examined and considered incurable by other otologists, 68 per cent. have been improved after treatment by this instrument; but such a result does not appear to have been obtained by others, and the opinion has been expressed that this good result is in part due to the effect of suggestion. This would now seem to be the opportunity to use both instruments in conjunction, and to test the actuality of the results of treatment by an exact measurement of the hearing, plotting out on charts the auditory field in a number of cases before and after treatment.

A MATTER OF PRINCIPLE.

Dr. Olive Langmead recently resigned her post as part-time officer for maternity and child welfare under the Bethnal Green Borough Council. For a number of years she had been using two brands of dried milk for infants who required to be artificially fed. The Public Health Committee of the Council passed a resolution that these brands were to be discontinued in favour of another, and Dr. Langmead sent in her resignation on the ground (1) that she could not undertake responsibility for the health of infants if obliged to use a brand of milk with which she was unfamiliar; and (2) that she could not accept dictation from a lay committee upon medical matters. We have gone carefully into the circumstances attending her resignation and are satisfied that it was in accordance with the ethical principles which govern medical practice. Contrary to popular belief, these are framed for the safeguarding of the public, and Dr. Langmead's action is justified by her estimate of her public responsibility.

THE BATEMAN APPEAL.

As already explained in The Lancet, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	482	16	0
Messrs. Amery Parkes and Co., Solicitors	5	5	0
Dr. Agnes Savill	2	2	0
W. M.	2	0	0
Thomas Laird	1	0	0
	£493	3	0

Remittances should be forwarded to the Manager of The Lancet, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

Royal Commission on National Health Insurance.—The thirty-second meeting of the Commission was held at the Home Office, Whitehall, on June 18th, Lord Lawrence of Kingsgate in the chair. Evidence as to the supply of medicines, drugs, and appliances under the insurance scheme was submitted by the Retail Pharmacists Union, represented by Mr. A. R. Melhuish and Mr. G. A. Mallinson; and by the Incorporated Society of Pharmacy and Drug Store Proprietors, represented by Mr. W. Huntrods and Mr. A. Hutchinson. Thereafter, Sir Cooper Perry and Dr. James Mennel, representing the Chartered Society of Massage and Medical Gymnastics, gave evidence on the question of including massage and medical gymnastics in the insurance scheme; and evidence as to dental benefit was given of behalf of the Ivory Cross by Mr. W. F. Mellersh, Mr. C. Davis, Mr. H. D. Grant, Mr. John Hall, and Miss A. E. Fletcher. The Commission announce that proof copies of the oral evidence and the relative statements submitted at the meeting of May 28th, 1925, may now be obtained from H.M. Stationery Office (2*s.* 3*d.*).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXVIII.

THE TREATMENT OF WARTS AND MOLES

Warts.

The common wart is of infective origin and auto-inoculable, and is most frequently seen on the dorsal aspects of the fingers, about the knuckles, and round the nail-folds. These villous papillomata are easily contaminated with dirt and therefore usually of a brown or blackish colour. In association with the "mulberry" tumours there are sometimes found a flat variety (*verrucæ planæ juveniles*) on the face, particularly of children, thus suggesting their contagious nature.

Local treatment in cases of multiple warts of children may be preceded by oral administration for a week or two of magnesium sulphate (dose according to age), or lime water, half a pint daily (Sequeira). Glacial acetic acid is the best local caustic and should be applied twice daily, the surrounding skin being protected with vaseline. Care must be taken when it is used on the face; a 5 per cent. solution of resorcin and salicylic acid in spirit is a better application in this situation. Ultra-violet rays from the Kromayer lamp in skilled hands will also effect a cure of this superficial type by causing a general exfoliation of the parts irradiated.

The thickened chronic warty growth on the knuckle may have to be attacked with the actual cautery. This is not necessarily a painful procedure, and in adults no anæsthetic is required. The cautery point should have a cutting edge which is allowed to sink vertically in parallel lines at a dull red heat into the excrescence until the patient complains of pain. This method is especially useful in cases in which the fold of the nail is involved.

Plantar warts, owing to their situation and configuration (apex of a pyramid directed upwards), are worthy of special notice as they cause great pain on walking. There may be a group of two or three such conical tumours on the heel or ball of the great toe. Pain is almost invariably relieved and walking rendered possible by surrounding the warts with a ring of felt, to take the weight of the body. The best curative agent is radium, an unshielded applicator of full strength being applied for an hour to an hour and a half.[1] The wart is usually extruded in about three weeks, within which time a further application should not be made. X rays (2 β dose), through a half millimetre aluminium shield, may be substituted for radium and given at intervals of ten days.

The *filiform* wart, most commonly seen on the mucous membrane of the external genitals, or on the lips, or on the skin of the eyelids, has probably the same ætiology as the flat wart. Its minute size and the delicate character of surrounding structures contra-indicates the use of caustics. Careful removal with the cautery is the simplest and safest procedure.

Venereal warts are usually massive cauliflower-like excrescences about the external genitals of persons with gonorrhœa or other specific infection in which discharges occur. They are easily contaminated with the organisms of secondary sepsis and soon become an exceedingly offensive complication. The anal mucous membrane may also be involved. Frequent washing with lotio nigra, and the liberal application of a 5 per cent. calomel dusting powder should precede more radical measures, and are sometimes successful in causing involution. Surgical ablation with the sharp spoon under anæsthesia is the usual procedure in these cases, but a more modern method which precludes the possibility of hæmorrhage is the diathermy current. The excrescences are well soaked in saline, a flat applicator electrode is held against them, and the current turned on slowly until they coagulate, whiten, and begin to steam, owing to the heating up to boiling-point of the contained fluids. Charring by spark discharge (fulguration) should be avoided. Frequent dusting with an antiseptic powder is the only subsequent treatment required. To prevent recurrences after removal it is, of course, essential to treat the associated specific infections. A few doses of X rays ($\frac{1}{2}$–$\frac{3}{4}$ β) through a $\frac{1}{2}$ mm. shield may be tried at weekly intervals when surgical procedures under anæsthesia are refused or inadvisable, and chemical caustics, such as pure phenol or acid nitrate of mercury, may also be used. In this case great caution must be used in protecting surrounding parts.

Seborrhœic warts occur in association with the seborrhœic diathesis on the scalp and cause annoyance by the constant trauma of the brush and comb. Here again the actual cautery is the best and cleanest ablation method; recurrences may be prevented by prescribing an antiseptic hair lotion. Another type of seborrhœic wart occurs on the back, flanks, and abdomen of predisposed persons of both sexes after middle-age. They are black or yellowish-brown in colour, associated with a greasy skin, and do not undergo malignant change. Sometimes pruritus is complained of and removal requested. Mild exfoliative doses of the Kromayer lamp (ten minutes at three feet) at weekly intervals, or the X rays ($\frac{3}{4}$ β unshielded) once or twice at an interval of 14 days, usually effect a cure, which has to be maintained by the daily use of a sulphur or sulphur-naphthol soap; this is sometimes effective without other treatment. More chronic isolated lesions can be removed by soap plaster or salicylic plaster (5 per cent.) applications, and if these fail recourse may be had to freezing ($\frac{1}{4}$–$\frac{1}{2}$ minute) with the carbon-dioxide snow pencil.

Warts which Tend to Ulcerate.

Senile warts, arsenical warts, warts from the constant exposure to sunlight, X rays, tar exhalations, paraffin and soot, have to be sharply differentiated from the foregoing types, as they not infrequently tend to ulcerate and to be transformed into epitheliomata. Senile keratosis or warty patches on the face or backs of the hands in persons over 60 are not uncommon in fair subjects, especially if they have lived in tropical climates. Usually the condition is associated with small areas of cutaneous atrophy and brown or yellowish pigment spots. In the other types which resemble the senile variety clinically, a history of causation is usually forthcoming. In such conditions removal of the warts should always be advised and may be effected with CO_2 snow, diathermy, or surgical excision. It should be remembered that ineffective radiotherapy may actually stimulate these growths, and for this reason X rays and radium should be employed by an expert only, or in cases which can be kept under observation for a long time.

Moles.

All moles are of congenital origin, although not always apparent at birth. They are arbitrarily classified as pigmented, non-pigmented, and hairy. In size they vary from a pin's head to a large area involving half the face or one buttock or even more. The treatment which is always sought for at some period or other of the patient's life, either on account of the disfigurement or for fear of subsequent malignant changes, must be guided by the size and situation of the anomaly. Once decided upon, radical procedures should not be postponed as moles grow with the child.

Small non-pigmented moles can be easily removed by freezing for periods varying from 40–60 seconds, according to their apparent depth in the subcutis. The ensuing blister should be pricked aseptically and then dressed with calamine lotion. The scab should never be forcibly removed but allowed to separate spontaneously. The procedure may need repetition.

---

[1] Vide Clinical Index of Radium Therapy (A. E. Hayward Pinch), pp. 40, 121.

Hairy moles, if very small, should be treated by electrolysis of the individual hairs. The pigmented elements tend to fade as the hair-bulbs are destroyed. Remaining pigmentation can be dealt with by freezing. For larger moles, especially when warty, excision followed by grafting or the application of diathermy as described in the section dealing with venereal warts, are the methods of choice. Radium, X rays, cautery, and chemical caustics are not advised in this type of mole.

Physician for Diseases of the Skin, Royal
Northern Hospital.

The Services.

ROYAL ARMY MEDICAL CORPS: OFFICERS FOR THE SUPPLEMENTARY RESERVE.

IT is officially announced by the War Office that commissions in the R.A.M.C. Supplementary Reserve of Officers are open to members of the medical profession engaged in civil practice. The object of this reserve is to complete and maintain the various medical units of the regular army at war strength on mobilisation, and the officers are divided into two categories. Those in the first category (Category B) have to undergo a preliminary training at the R.A.M.C. depôt, and an annual training of 14 days with a selected formation or unit of the regular army. The preliminary training lasts normally for six weeks, but in the case of officers holding Certificate A or B medical, of the Officers' Training Corps, it is either dispensed with entirely or limited to three weeks. The other category (Category C) is intended for medical men with previous service and those possessing special professional qualifications. Officers in this category are not required to do either preliminary or annual training. The present requirements include a number of specialists in surgery, medicine, mental diseases, X rays, pathology, bacteriology, and hygiene, who will as far as possible be employed in their special subjects on mobilisation.

All commissioned officers are paid an annual gratuity of £25, and those in Category B in addition receive pay and allowances as for regular officers during all training. Normally, an applicant's age should not exceed 32, but this limit may be dispensed with in special cases. The rank of appointment is that of lieutenant. Promotion in Category B will be to captain after three and a half years' commissioned service, to major if qualified after 12 years' commissioned service, after which period officers will be transferred to the Regular Army Reserve of Officers; in Category C promotion to captain after three and a half years' commissioned service, and after ten years' service transferred to the Regular Army Reserve of Officers. A candidate for Category C who served as an officer in the R.A.M.C. during the late war will be allowed to count such service for rank on appointment, for promotion to captain, and towards the ten years period of service preceding transfer to the Regular Army Reserve of Officers. Forms of application for appointment can be obtained on written request to the Under-Secretary of State for War (A.M.D.1), War Office, Whitehall, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE.

H. L. Bernstein and H. W. Strong to be Surg. Lts.

ROYAL ARMY MEDICAL CORPS.

Capt. D. A. Chalmers is granted the temp. rank of Capt. and relinquishes the rank of Capt.

ARMY RESERVE OF OFFICERS.

Maj. C. H. Hopkins, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Supernumerary for Service with the O.T.C.: Maj. A. E. Webb-Johnson resigns his commn. and is granted the rank of Col. with permission to wear the prescribed uniform.

Edinburgh University Contgt. (Medical Unit), Sen. Div.: Lt. N. Kerr to be Capt.

ROYAL AIR FORCE.

Flying Officer L. P. McCullagh is granted a permanent commission in the rank stated.

Flight Lt. W. G. L. Wambeek is promoted to the rank of Squadron Leader.

Special Articles.

THE MILK-SUPPLY AND ITS IMPROVEMENT.

BY WILLIAM G. SAVAGE, B.Sc., M.D. LOND.,
COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

III.—REMEDIES TO IMPROVE THE MILK-SUPPLY.

(*Concluded from p. 1314.*)

Grading of Milk.

SINCE milk is one of the few foods not graded, and since there are material differences in the quality of milk as supplied, it is but logical to suggest that milk also should be graded according to its quality. The unanswerable objection is that milk is too valuable as a food to perpetuate the poorer grades of milk as the inevitable food for the poorest, and it is scarcely an adequate answer to say they get it now. Two distinct procedures have been tried. The English plan, the legal sanction for which is contained in the 1922 Milk Act, merely provides for certain superior classes of milk (Certified, Grade A (tuberculin tested), and Grade A), and leaves the rest of the milk-supply untouched. Its value is educative and few would suggest that it is more, or that it is a serious contribution to a purer supply. As an educative influence undoubtedly these graded milks have done much good. They would do a good deal more if they were not hampered by their having to be administered by three different authorities, an illustration of the muddle our local government system has passed into owing to the overlapping of authorities. The principle should be extended and completed logically by having a Grade C (see below) for very contaminated milks.

The other plan of grading is to grade the whole of the milk-supply, and this has been adopted in some cities in America. Originally, as in New York, there were three grades, A, B, and C, but now different milk ordinances include a bewildering variety of grades. There is great lack of uniformity both as to the number of grades and the methods of assessing each grade. The latter is sometimes bacteriological alone, for others a mixture of bacteriology and score card methods. To put in force in this country such a system would mean a revolution in our methods of control, including an extensive and sustained system of bacteriological examinations and the provision of an adequately trained body of special inspectors. At the present time it is not practical politics, and a number of valid objections can be raised which are not easy to overcome.

Clean Milk as a Business Proposition.

The elimination of the dangers of milk as a vehicle for the spread of tuberculosis and acute diseases is a different question from what may conveniently be called the "clean milk" problem. For the latter a good deal can be done by a firmer and more efficient legal control, still more by direct educative influences brought to bear upon producers and distributors, but the problem is likely to remain a problem until effective steps are taken to make clean milk handling a better business proposition than dirty milk handling.

To make this clear it is necessary to look at the matter from the angle of view of the milk producer and distributor. The milk producer is a farmer who is not actively hostile but usually finds considerable difficulty in visualising his deficiencies as regards the case of milk. This difficulty is not lessened by the fact that the majority of sanitary inspectors who supervise him have but a limited appreciation of what clean milk means, and are very apt when they do take action to concentrate upon the need for expensive buildings and to neglect essentials of methods. As a farmer he is bound to conduct his milk production on business lines—in other words, he wants to produce milk at the lowest possible cost and sell it at the highest possible price. It costs more to produce clean milk, but unless he produces a specially clean article which he can label as a graded milk and sell at a higher price, he obtains no more for clean than for dirty milk. For the ordinary producer the scales are weighted in favour of dirty milk. The solution is to make the balance tip the other way. Simple education of the milk trade without a concrete business objective has been tried for 20 years and more and has done very little.

Such a solution may be sought along several lines. One is to make the consumer realise the kind of milk he should receive and insistently demand it. The distributor will then have a direct incentive to supply clean milk and will take steps to obtain and supply it. Up to the present I have failed to find a distributor who will give a better price for clean than for contaminated milk. In the absence of an insistent demand there is no inducement for him to do so.

In this connexion it must be admitted that the medical profession does not fully utilise its opportunities. Individual members often fail to impress upon their patients the necessity of obtaining their milk from satisfactory sources, and producers of graded milks have complained to me that they have not obtained the support of medical men in their districts in their endeavour to provide a pure supply. As members of hospital staffs they are usually in a position to stress the need for the hospital milk-supply being of high bacterial quality, but it seems to be the exception for this to be done. Within the last few months, through the courtesy of the hospital secretaries, I have obtained particulars of the terms of the contracts for milk for six large voluntary hospitals. Four of them impose no conditions as regards bacterial purity, one requires the milk to be Grade A, one makes no bacterial stipulation, but submits samples periodically to the hospital pathologist for bacteriological examination. Insistence upon reasonable standards of bacterial purity would not only benefit the hospital but serve as a valuable educative influence upon the production of a cleaner milk-supply. A second line is to make the producer and distributor realise that the consumption of fresh milk is influenced by the quality of the article supplied, and that an increase in the supply of fresh milk and a diminution of the use of preserved milks can be materially stimulated by the supply of a better quality article. A third line is to penalise really bad milk and make it unsaleable. This must operate by eliminating the hopelessly bad producer, and by stimulating the mediocre producer to better his methods. In my opinion it is essential that this third line of action should be made to operate, but the method of doing it requires careful consideration.

Unless specially trained and efficient inspectors are available it is dangerous to make this power dependent solely upon the results of inspections of the conditions of milk production. After all, the essential point is whether or not reasonably clean milk is being obtained, and this can best be judged by direct bacteriological examination of the milk. The existing grades should be augmented by a degraded milk—Grade C, milk below any reasonable standard of purity. The production of such a milk would be suspected by inspection, proved by bacteriological examination. If after several warnings conditions were not considerably improved, the milk-supply from that producer would be labelled *Grade C*. It should be illegal for any wholesaler to mix it with other milk, and it could only be sold as Grade C and also marked "inferior quality milk, which should be boiled before use." Milk could only be removed from that grade after definite alteration of quality, as shown by an improvement of methods and production and a series of bacteriological examinations, paid for by the producer. The conditions for Grade C would be laid down by the Ministry of Health, and could be so drawn as to include at the outset only thoroughly bad milk, to be tightened as average conditions improved.

The beneficial effect of such a logical addition to the grades would extend far beyond the actually small number of producers so penalised, since the knowledge of its existence would have a highly salutary educative influence. It would in practice only penalise the small number of incorrigible producers whose methods and practices are a disgrace. The average producer should welcome it, since it would remove the unfair competition of milk of this type.

Bacteriological examinations of milk are extremely valuable in connexion with efforts to produce a pure supply.[1] Their greatest utility is as a sorting agency, and to see that graded milks maintain their stated standards rather than as a means of fixing bacteriological standards, failure to comply with which is a punishable offence, a procedure in favour in some American cities.

The Bogy of Increased Cost of a Better Milk-Supply.

The opponents of a better milk-supply always advance the argument that a pure supply means increased cost and whatever we do we must not increase the cost of milk. The argument is not very convincing, and might be applied to every foodstuff. We have witnessed, from the action of economic causes, an enormous increase in the retail price of milk, but there is little evidence that it has materially affected the consumption of milk. A cleaner milk will ensure a larger consumption of milk, yielding a bigger profit and so possibilities of reduction on the retail price. Milk is no exception to the ordinary business postulate that a good article pays its way. Purely as an *agricultural* problem it is arguable that when the routine had been acquired a clean milk would pay itself from the saving of pasteurisation, prevention of losses on soured milk, and increased health of cattle from a diminution of bovine tuberculosis. There is no real reason why the provision of clean milk should send up the cost of production appreciably and more than temporarily. Many thousands of milk producers do supply good milk at ordinary prices and make it pay.[2] The committee on the production and distribution of milk pointed out that there are numerous ways (eight are given), many now neglected, by which the costs of milk production can be reduced. If it is so important to keep down the cost of milk, why allow these to be neglected and fasten attention on the one factor which is of public health importance ? To take but one of them, there are many thousands of farmers who never keep milk records, and who, in consequence, are milking cows which are absolutely uneconomic. This one reform alone would pay all the additional costs of the difference between producing clean milk and the present average quality milk. This cost bogy argument should leave the medical profession cold.

While the cost of production and of distribution need not be materially increased for average clean milk a distinction must be made as regards the cost of supervision. Undoubtedly the cost of supervision must be considerable, especially if part of a system to eradicate tuberculosis. This should not fall upon the milk trade, and therefore would not affect the retail price of milk. It is part of the general public health expenses of the country. The greater part of the milk of the nation is produced in the rural areas while most of it is consumed in the urban districts. There is, therefore, considerable justification for the plea that material contributions towards the cost of supervision should be made by the urban areas. Under our present system of government such financial assistance can best be given by grants in aid from the Ministry of Health to pay part of the costs of supervision. This would also have the effect of making for efficiency and for uniformity of administration since neglectful authorities would lose their grant.

---

[1] See article by the writer: World's Dairy Congress, 1923, Proceedings, vol. ii., p. 1295.

[2] My home supply is a milk bottled at the farm, and which consistently contains far fewer bacteria than the legal limits of Grade A, and it is delivered to me at the price of ordinary milk.

Another favourite argument advanced, that proper milk control means new hordes of officials, is singularly inappropriate when applied to milk. Control over the satisfactory production and handling of milk is best judged by bacteriological methods. Such methods can pick out with tolerable certainty and uniformity the milk producers and others whose methods of handling milk are below a reasonable standard. One bacteriologist can examine a very large number of samples per day, and with his help the number of field inspections required is immensely reduced. Attention can be concentrated upon the worst and a steady levelling up process inaugurated

Summary of Remedies Proposed.

With a subject of such magnitude as the milk problem, and one which has been the object of so much detailed study, it is impossible to cover every phase in the limits of space available. What has been attempted has been a rapid survey of the present position and an outline of those remedies which seem to me to be of most utility. As regards these remedies the most essential may be summarised as follows :—

1. A continuance of the present system of grading, for its educative influence, but with the addition of a *Grade C* milk designed to repress the very dirty minority of producers.
2. Systematic efforts to educate the consumers to appreciate the importance of good quality milk and the value of milk as a food. Education of the milk trade as to the need for improvement in methods and the financial advantages involved. In connexion with such educative activities the medical profession could play a powerful and influential part if they were agreed as to the lines to follow.
3. Additional legislation : (*a*) To enable effective powers to be obtained to deal with bovine tuberculosis. (*b*) To define the minimal requirements of clean pure milk and provide for their compliance. (*c*) To give extended control to prevent the infection of milk with pathogenic bacilli. (*d*) To simplify the control over milk by its entire transference to the larger local authorities. (*e*) To provide for the payment of grants in aid from the Treasury through the Ministry of Health towards the cost of the supervision over milk production and distribution.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

French Vital Statistics for 1924.

THE figures recently published by the Ministry of Labour, Hygiene, and Social Welfare give an instructive summary of the relation of births to deaths in France during 1924. There were 752,101 births to 679,885 deaths, or a surplus of 72,216—a surplus which, considering the greatness of the numbers concerned, is a very small margin on the right side. The excess of births over deaths per 10,000 inhabitants was 19 in 1924 as compared with 24 in 1923, 18 in 1922, 30 in 1921, and 41 in 1920. It is extraordinary, one might even say amazing, that this excess between 1920 and 1924 should have fallen from 41 to 19 per 10,000 inhabitants. Since 1920, when the number of live births throughout France was 834,411, there has been a marked decline in this figure ; in 1923 it had fallen to 761,861, and in 1924 it was further reduced to 752,101. In 1920 there were 213 live births for every 10,000 inhabitants, whereas in 1924 this figure was reduced to 192. Local differences in the " coefficient of natality " in 1924 were considerable. Thus, in Pas-de-Calais there were 306 live infants born per 10,000 inhabitants, whereas in the Côtes-du-Nord this figure was only 230. The number of infants born dead, or dying before registration, showed the same decline as that in the number of live births. The divorce statistics showed some curious fluctuations. The year 1921 seems to have marked the crest of the present divorce wave with a total of 32,557, the number of divorces in 1924 being only 21,033. In 1900 there were only 7363 divorces, and in 1913 this figure had jumped to 15,372. Divorces, it would seem, are largely a matter of fashion and are probably much more subject to such influences as suggestion than are births and deaths. A comparison of the numbers of divorces in the different areas indicates that industrialism gives rise to conditions favouring divorce, the highest divorce figures being found in the industrial Departments, and it is instructive that, while in one industrial area there were as many as 241 divorces per 100,000 inhabitants (Department of the Seine) there were only 23 divorces per 100,000 inhabitants in another area (Côtes-du-Nord). With regard to the narrow margin between the births and deaths in France, the modern tendency is to widen this margin rather by measures calculated to improve the general health and add to the longevity of the living than to swell the numbers of the new-comers.

Copyright of Medical and Pharmaceutical Lectures.

The eleventh Chambre Correctionnelle has recently been the scene of an interesting lawsuit concerned with the copyright of the spoken word. A publisher, Mr. Lambert, had made use of shorthand notes of lectures given by professors of the faculties of medicine and pharmacy, circulating these lectures weekly to his subscribers. In the course of the judgment passed by the Chambre, which imposed a fine of 50 francs on the publisher, it was stated that " the laws concerning copyright apply to the spoken word, particularly to the lectures of professors." Each of the professors whose lectures had thus been published without their previous consent was awarded 100 francs in damages. No one in court recalled the precedent of a hundred years ago when Sir Astley Cooper and John Abernethy bitterly resented the publication of their lectures in THE LANCET. It is not yet clear what effect the decision of the French court will have on the reporting of lectures and proceedings of medical societies, but the guess may be ventured that there will be little change. Indeed, as most professors are human, or nearly so, it is probable that if their spoken words were to be held strictly sacrosanct and respectfully ignored, more pain would be inflicted than if a verbatim report were to be given all the publicity at the command of the most pushing of impresarios. A verbatim report is, by the way, to the carefully edited report what the amateur photograph is to the touched-up product of the professional photographer, and it is sometimes an act of refined cruelty to broadcast every word of a volubly inaccurate speaker. Provided public speeches are edited as well as reported fairly (in fairness to the speaker rather than to the audience), there is seldom much likelihood of questions being raised either in France or in England as to the copyright of the spoken word.

Presence of Tubercle Bacilli in the Pharynx of Infants with a Positive Skin Reaction.

The tuberculin skin test is of absolute and indisputable value in the difficult matter of diagnosing tubercle in infants, but it is also of importance to know whether the infant, like the tuberculous adult, is liable to spread contagion. The infant, of course, does not sin by spitting, and the search for the tubercle bacillus in the pharyngeal mucus, taken directly or by means of lavage from the stomach, has given very inconstant results. The very small number of bacilli which may be present are found with great difficulty. Drs. Lesné and Langle conceived the idea of injecting this pharyngeal mucus subcutaneously into a guinea-pig. The results of their experiments showed that two-thirds of the infants with a positive skin reaction, who were infected with tubercle in either a latent or an active stage, carried virulent tubercle bacilli in the pharynx. On the other hand, injections made from infants with a negative reaction produced no effect on the guinea-pigs. The bacilli are probably derived in most cases from pulmonary lesions opening into the bronchi. Yet if no pulmonary lesions were discoverable on radiographic examination, which is not uncommon, or if the infant has succumbed without a caseous focus being located, it may be permissible to suppose that the pharynx was not the portal of exit of the bacilli but the portal of entry. The organism might be present in the pharynx and, without apparent lesion of the mucous membrane, might infect the subject. However that may be, we should not regard infants with a positive skin reaction as non-contagious, although they do not spit. They may infect healthy children with whom they are placed in contact, either directly or indirectly by the medium of such articles as indiarubber teats, spoons, and towels. Therefore, before allowing infants with a positive reaction to associate with non-tuberculous children, the pharyngeal mucus ought to be tested by inoculating a guinea-pig, and, if it is thus proved infective, all necessary precautions should be taken.

The Vaccine B.C.G.

Before the Academy of Medicine Dr. Calmette recently gave the clinical and experimental results of preventive vaccination against tuberculosis in new-born children by means of the vaccine Bilié-Calmette-Guérin, known as B.C.G. Many doctors make use of this vaccine, especially in cases where the children have been born in a home in which tuberculosis is already rife. The results have been very satisfactory. Not one of the 178 infants vaccinated three years ago has died of any infection which might be called tuberculous; 94 of them which were recently examined are in perfect health and their growth has been normal. From July 1st, 1924, to June 1st, 1925, 2070 new-born infants were vaccinated by the B.C.G. supplied by the Pasteur Institute without any untoward results. The method of vaccination consists in administering three doses of the vaccine in a teaspoonful of milk at intervals of 48 hours when the baby is from 3 to 10 days old; 137 of these children vaccinated in this way in families where the exposure to tuberculous infection was great have not furnished a single case of death from tuberculosis, while on the other hand the mortality of unvaccinated children under the same conditions stands at 32·6 per cent. in Paris during the first year of life, and at 24 per cent., on the average, for the whole of France. The experiments show that the vaccine B.C.G. confers on monkeys and young calves obvious powers of resistance to tuberculous infection, whether the latter is natural or artificial. It would appear therefore that this method of tubercle prevention in young children might be regarded as having no dangers and that its efficacy is beyond question. Further observations and the time factor will enable more definite pronouncements to be made on the practical value of this prophylactic measure.

Monument to the Members of the Paris Medical Faculty who Fell in the War.

A monument raised to the memory of the doctors and medical students who died during the war was recently set up in the medical faculty of Paris. The monument, which has been placed in the Salle des Pas Perdus at the foot of the staircase which leads to the library, is a bas-relief designed by the sculptor Raoul Besnard. It represents a corner of a battlefield where, on the right, a young military doctor in a pensive attitude is gazing at a group of stretcher-bearers carrying a wounded man to the aid-post. Above, the inscription runs "Facultas Parisiensis erexit suorum memor, 1914–1918," and beneath are placed the names of nearly 500 doctors or students of the faculty who died for their country. The President of the Republic performed the unveiling ceremony and was assisted by Mr. Appel, the Rector of the University; Mr. Colville, the Director of Higher Education; Mr. Rouget, the Director of Sanitary Services; Mr. Guillaumin, President of the Municipal Council; Dr. Roger, Dean of the Faculty of Medicine; and several other dignitaries, including the President of the Academy of Medicine. Speeches were delivered by the representatives of various medical bodies. Prof. Chauffard spoke for the Société des Amis de la Faculté de Médecine de Paris, by whose efforts subscriptions had been secured to raise the monument, and Mons. Beau spoke on behalf of the students. A poem composed by Prof. Charles Richet was declaimed by Mlle. Madeleine Roche, of the Comédie Française.

THE VIENNA EXHIBITION OF HYGIENE.

(FROM OUR OWN CORRESPONDENT.)

IN May of this year there was opened in Vienna an Exhibition of Hygiene which is attracting large crowds of visitors and which will add considerably to general knowledge of this subject. The exhibition consists of three distinct sections. The first section deals with man, his anatomy and physiology; the second with hygiene in general, and the third with the modern household from a hygienic view. The dominating idea in promoting the exhibition was that hygienic knowledge and hygienic empiricism should become the common property of the public.

The Anatomy of Man.

By means of large wax and plaster-of-Paris models, diagrams, and pictures of the different parts of the body, by comparative charts and original wet and dry specimens of anatomical and physiological interest, the lay public is enabled to learn what kind of machine the human body really is. The value of social hygiene, the knowledge of the laws governing the development and destruction of life—in short, the "legislature of living"—is impressed on even the most unobservant and incurious visitors. The section pertaining to man in general has been brought over from Dresden, where it formed the bulk of the celebrated hygienic exposition there. It is subdivided into sections dealing with prehistoric development of mankind, the osseous system, the muscles, the organs of nutrition, respiration, circulation and secretion, the brain and nervous system, and the organs of the senses (eyes, ears). Dynamometers, accessible to every visitor, show the "man in the street," what force is exerted by his own flexor muscles of the hand, or how the jaw is able to exert a pressure of more than 50 kilos to the square centimetre in cracking a hazel-nut. The method of converting food articles into energy, as effected by the digestive organs, is explained by means of large models. An exhibit called the "transparent man" is a great attraction. It consists of a collection of specially treated specimens, made transparent or translucent without dissection. By means of a secret process, entire organs, like the legs or arms of babies, the stomach of an adult, the pregnant uterus at various stages, the adult kidney or heart, have been made so transparent to strong light that all the details are visible. The collection shows well the development of a human embryo from the fifth week up to birth, the centres of ossification, and the gradual development of all other organs. The exhibit is contained in a dark room, and the objects are viewed against strong electric light.

Hygiene and Public Health.

The second section of the exhibition, which is devoted chiefly to the problem of hygiene, is subdivided into individual hygiene, collective hygiene, and general hygiene or public health. The leading idea is here also to impress upon the mind of the visitor the necessity of adapting life to the laws of hygiene—i.e., cleanliness, soberness, ventilation. Diagrams, charts, pictures, and statistical data serve this purpose. Thus numerous pictures illustrate the ways of infection with tuberculosis; dust inhaled by children, contamination by spitting, playing in the gutter, eating dirty food, kissing or careless coughing by diseased persons are shown—in rather crude pictures—to be the potent source of propagating all sorts of illness, especially tuberculosis. We see also the prophylactic measures taken by large institutions, such as the sickness insurance clubs or *Krankenkassen*, to promote the health of their members. The ravages caused by tuberculosis and syphilis are illustrated in statistics taken from the reports of hospitals and lunatic asylums, and the results obtained by modern methods of treatment never fail to make a strong appeal to the uninitiated in these matters. A fairly large space is devoted to the infection of the body with parasites—tæniæ and nematodes and trematodes, as well as trichinæ are not infrequent in Austria, especially in rural districts—and their life-cycle, their methods of invading the host, as well as the ways to combat them are shown, and the infection of the blood with plasmodium is explained. Alcohol and its effect upon the organism receives prominence. Apart from the loss of money entailed by the nation's expenditure upon alcoholic beverages, the actual damage done by indulgence in alcohol to the liver, the brain, the kidneys, and the procreative organs is shown both in pictures and in wet and dry specimens. Statistics from lunatic asylums form a useful weapon in the fight against alcohol, which is slowly gaining ground in this country. The increase of total abstainers amongst the working classes, as proved by the membership of anti-alcohol clubs, is 60 per cent. in two years, but is still far from being general. Also the anti-nicotine movement is represented in the exhibition, chiefly by the products of a factory where, by a special process, 95 per cent. of the total nicotine contained in tobacco is removed. This movement is not very much patronised. A special part is devoted to the exhibits of the "Society of the Flame" (cremation).

Specimens Exhibited.

Amongst the numerous other exhibits, medical men will be interested in the collective expositions of the Vienna clinics. The surgical clinics have assembled collections of renal and vesical stones, of specimens showing injuries and diseases of the bones, and photographs demonstrating plastic surgery of the face; the internal clinics show pictures and photos, with explanations, of endocrine cases, of tuberculosis and its treatment, of blood diseases, and other special clinics make exhibits of their specimens. The excellent effects of open-air sports, swimming, and gymnastics on the adolescents or weakly children are well shown in a series of photographs taken from children's open-air colonies.

The value of the exhibition is increased by the exhibits of municipal and State authorities, showing the results obtained by introducing pure drinking water supplies to towns and cities as well as drainage arrangements. Free public lectures on a wide variety of subjects are given by eminent men every evening. Nearly all these lectures are illustrated by cinematographic demonstrations and have become a favourite attraction for visitors. The exhibition closes in July, but negotiations are taking place to make the exhibition, or part of it, a permanent institution like that in Dresden, for the benefit of the public, and there is little doubt that the attempt will be successful.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

THE POOR-LAW COMMISSION.

THE chief witness examined at the last meeting of the Commission on the Poor-laws was Dr. E. F. Stephenson, chief medical officer of the Department of Local Government and Public Health, who gave information as to the policy of the Department in regard to local hospitals. He said that it aimed at centralisation in each county, and that the county hospitals were fully supplied with X ray apparatus and other equipment. Since county infirmaries were taken over it was necessary to make arrangements for the people who were able to pay, and provision was now made for paying patients. Their great aim was to provide suitable treatment for the sick poor.

Hospital Medical Officers.

The minimum qualifications required for a medical officer of a county hospital were three years' regular practice of his profession, and at least one year's practice in surgical work. As regards surgeons, their aim was to employ full-time men for the county hospitals in which there was sufficient work. The usual salary was £500 a year, with free residence and the right to accept fees from certain patients in his hospital. The idea was if the beds were not required for poor patients they could be used for paying patients, but the first claim was that of the poor patients, except in very urgent cases, such as appendicitis. Whole-time medical officers in county hospitals were prohibited from taking outside practice, except as consultants. Questioned as to the advisability of having hospitals available within a radius of eight or ten miles for poor patients, he did not consider it necessary, as motor ambulances facilitated the transfer of patients. He did not think the hospital accommodation was sufficient in every case—e.g., in Co. Galway, where four cottage hospitals would be required. Dealing with vaccination, he said their vaccine department was a very good one, and every tube of lymph was examined three times before being issued to the public. Vaccination was well enforced, except in Co. Wexford and in some parts of Donegal. He also stated that the Minister for Local Government intended to introduce a Bill setting up a Selection Commission for the appointment of medical officers, the idea being to take the power of appointment from the local bodies.

Appointment by Selection Commission.

The most important part of Dr. Stephenson's evidence is that contained in the last paragraph. It is now generally admitted that even when acting with the purest intention, a local elective authority is not a body which can estimate accurately the professional standing and experience of candidates for medical appointments. In too many instances, notoriously, the members of the local authority have been entirely swayed by political and family influences. The Minister may, therefore, be congratulated on his decision. But the setting up of a Selection Commission is not a complete solution of the problem. Every committee of inquiry which has investigated the Poor-law medical service of Ireland has come to one conclusion, that the only satisfactory way of dealing with it is by transforming it into a national medical service with entry by competitive examination.

In Dr. Stephenson's evidence in regard to county hospitals, he stated that the usual salary for a county surgeon was £500 a year, with the right to consulting, but not to private practice. This salary is not sufficient to attract suitable men, and as a matter of fact, it has been difficult in the case of some recent appointments to obtain any candidates with appropriate qualifications.

Public Health Work in the Free State.

In the discussion on the vote for the Department of Local Government and Public Health in the Dail recently, the Minister, Mr. Burke, gave interesting information in regard to some of the activities which come under the supervision of his Department. Dealing with maternity and child welfare services, he said that infant mortality in 1924 was the lowest on record. The rate in urban districts was 102 per 1000, and in rural districts 55 per 1000, being an average of 10 per 1000 lower than in the preceding ten years. Under the schemes for the provision of meals for school-children, three county boroughs and 23 urban areas had been authorised to make expenditure for this purpose. Such expenditure was incurred during the year in only two county boroughs—Dublin and Cork—and in 13 urban districts. The urban authorities had been repeatedly reminded of their powers in this respect. But during the year schemes were only adopted in Clonmel and Rathmines. During 1923–24, 11,000 children were fed, of whom

5596 were in Dublin. The total cost was £12,762, and the amount authorised £5313 as a grant. The medical treatment of school-children would be dealt with under the new Act, but the medical administration of that Act would not come into force till October next.

Dealing with tuberculosis grants, Mr. Burke said full schemes were in operation in 22 counties and two county boroughs, and partial schemes in other areas. As a result of the compulsory notification of tuberculosis there would be a substantially larger number of patients in the future. During the year a new sanatorium had been opened at Renmore, Co. Galway. That institution was already full, and its extension was under consideration. The general mortality from tuberculosis had decreased considerably in recent years. It was 2·9 per 1000 in 1904, and in 1923 it was 1·41.

Rockefeller Fellowships in Public Health.

A Selection Committee appointed by the Minister of Local Government and Public Health has chosen three names for the Fellowships in Public Health offered to the Irish Government by the Rockefeller Foundation. The selected candidates are John D. Carroll, M.B. N.U.I., Robert Condy, M.B. Dub., and James A. Harbison, M.B. Belf. All of them possess the Diploma in Public Health, and have already been engaged in public health work. Two of them (Dr. Carroll and Dr. Condy) had war service in the Royal Army Medical Corps. The new Fellows will study in the United States for a period of six months, according to a programme to be arranged by the International Health Board of the Rockefeller Foundation. They have pledged themselves to accept appointments as county medical officers of health on their return to Ireland.

Research Work in Mental Disease.

The Minister for Local Government and Public Health, in a letter addressed to the Joint Committee of the Grangegorman Mental Hospital, has suggested the establishment of an institute for pathological research in connexion with the hospital. He states that the scheme in its scope should extend not only to original research, but also aim at providing a pathologist capable of advising the medical officers of Grangegorman and the officers of such other mental hospitals as would lend financial support to the scheme. Further, the laboratory would be a centre in which post-graduate work in this special department of medicine could be undertaken; and it might be anticipated that in time assistant medical officers, who at present go to England for instruction for the period of their study-leave, could obtain in Dublin a course of instruction equally valuable.

The Committee referred the letter to the consideration of their medical superintendent, Dr. J. O'C. Donelan, who, in reply, expressed the opinion that a pathological laboratory at Grangegorman might be developed into a valuable centre for work and study, but he did not think there could be much field for it in the immediate future, as there were at present three excellent schools of pathology in Dublin—Trinity College, University College, and the College of Surgeons—who would, he is sure, give any help desired. The bigger scheme hinted at by the Minister might be developed later. A scheme for a central laboratory for all the Irish mental hospitals would involve the appointment of a really first-class man devoted to pathological work, who would require one or two assistants. The best results would be obtained by beginning on a small scale.

The scheme put forward by the Minister was strongly urged by the medical profession some 25 years ago, but the Government of the day postponed their support. Up to the present the pathological work done in Irish asylums has been trivial in amount.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(Continued from p. 1151.)

The Commission resumed its sittings on June 19th, Mr. H. P. Macmillan, K.C., the Chairman, presiding.

Evidence of Two Members of the Wandsworth Board of Guardians.

The first witnesses were Mr. George Hill and Mrs. Glanville, two members of the Wandsworth Board of Guardians. Their submission was that the method of visitation carried out until a year or two ago, when the patients on visiting days were brought up and passed before the visiting guardians, was useless, and that in order to be of any real service there should be informal unnotified visitations, the guardians actually seeing patients in their usual conditions and surroundings. Section 201 of the Lunacy Act permitted these visits between 8 A.M. and 6 P.M. on any day, unless the medical officer stated that such visit would be injurious to a particular patient or patients. Mr. Hill said that when, five or six years ago, he first became a guardian he was told he could not visit the patients unless he intimated his wish beforehand. Asked whether the visitation as now carried on—namely, without prior notification—was considered an efficient safeguard against ill-treatment or other irregularity, Mr. Hill said he thought it was, and if a report was made by a patient and it seemed well founded, he reported it to his board. His committee (a special visitation committee) was not satisfied with the herding together of about 100 patients which in places obtained, and he thought there should be a classification according to the mental condition of the patients. In some institutions when these visits were paid there was considerable delay before the visitors from the board were admitted. At first, until he insisted, he did not see the patients in the wards in their actual every-day conditions.

Mr. Hill said he objected to puerperal patients being put into insane wards; they should rather be regarded as subjects for after-care, especially as they were usually quite harmless.

Mrs. Glanville said there were four large asylums within a three-mile radius at Epsom, and suggested that the very acute cases should all be in one building, and the other three should be set apart for cases according to their stage of recovery, the last being the institution from which they were discharged. More nurses and attendants would be available for the acute cases, and less would be needed for those requiring less attention and watchfulness, and in this way there would be economy in working.

The Question of Punishment.

Mr. Hill said he was satisfied that punishment went on in these institutions, and this would not have been known but for the efforts of the special visiting committee. He related a case of ill-treatment, which even the doctor did not know of until five days afterwards, and members of his committee were not allowed to go to the institution and interview the nurses and attendants concerned in it. On their next visitation this particular attendant was temporarily missing. An inquiry was held by the Board of Control, but at that inquiry the visitors were not allowed to be present. He believed the attendants in such a case stood by each other and would not divulge incriminating information.

Mrs. Glanville said that if Mr. Hill and she had been at the inquiry they would not have agreed with the report which was made, and they would have said it had come to their knowledge that punishment of patients was going on. It was possible to punish a patient without leaving a mark. In a case at Hanwell it was at first denied that there had been punishment inflicted by an attendant, but at the next visit the patient in question had two black eyes, and they were told that the attendant had been dismissed.

Mr. Hill explained that the visitors did not interest themselves in the release of the patients from the institution; they recognised that was a medical matter. In another case inquired into, a great deal of a girl's hair had been pulled out of her head. He had known a man put into the acute ward by way of punishment, for it was well known that there the other patients would punish him, for they fought among themselves. The witness said he was prepared to fully substantiate the statements he was making. At the time in question the man had been in the acute ward three or four days, and the reason given for putting him there was that he had tried to escape.

Padded Rooms.—Clothing.

Mr. Hill said he considered the padded room at Cane Hill Mental Hospital was a bad one; it was too dark and there was not sufficient ventilation. In reply to questions, he said he paid his visit on a winter afternoon about 3.30 to 4 o'clock; he agreed that in such a room, for violent patients, it was necessary to have windows high, out of the patient's reach, because of possible injury by the glass. The Chairman and Lord Russell mentioned that they had both seen the room in question.

With regard to the clothing of the patients, the witnesses said that at Hanwell in the winter a number of the male patients were obviously cold and miserable, and their clothing was far from adequate. When a doctor there was spoken to about it he said that if good clothing was supplied the patients tore it off. Mrs. Glanville said the clothing at the other mental institutions visited was better than at Hanwell, and she did not know why there was that difference. Both witnesses preferred that patients should be allowed to wear their own clothing if it was suitable; any approach to a uniform was resented by sensitive patients. Mrs. Glanville said that she considered a visitation paid unannounced to a few patients in their ordinary surroundings was more valuable than a formal parade at a set notified visit. Senile cases were put into comfortable quarters by themselves, they were not with the acute cases.

The St. Luke's Mental Clinic.

Evidence concerning the working of the St. Luke's Mental Clinic attached to Middlesex Hospital was tendered by Dr. R. W. Gilmour. He said St. Luke's was one of the oldest of the registered hospitals. For many years it received only certified cases of insanity. It was decided to open a clinic, with an out-patient department and a few beds for more serious cases, and Dr. Hubert Bond suggested that an effort should be made to become attached to a general hospital. Accordingly, in 1923 the clinic was established with six beds. The nursing staff was supplied by St. Luke's Hospital. Reasons for founding the clinic included the fact that many people would go more readily to the out-patient department of a general hospital than to a mental hospital on account of the name of the latter, though that chiefly applied to people who knew but little about mental hospitals. Also, the fact of going to a general hospital caused them to realise that they were ill, and this recognition helped the treatment. In most illnesses expert examinations were necessary, such as of the ear and throat, and in such a clinic this and laboratory examinations came into the usual routine. This clinic was actually under the same roof as the Middlesex Hospital. The hospital neurologist and he saw the cases in the same room, and there was intimate association between the ward for mental cases and the other wards of the hospital. He believed that by treatment at such clinics many cases were prevented from reaching the certification stage. Patients came of their own desire and expressed wish, and when they arrived they were told they must obey the rules of the hospital. If they seemed likely to give trouble he told them he was taking their word, and that was mostly effectual. If it should happen that a patient was found unsuitable for the clinic he called upon the friends to remove him; noisy patients likely to disturb the others he would not keep there. He had not yet had any cases of suicide. In answer to Sir David Drummond, he said he thought an extension of the system in a general way would be a very good thing. But such clinics should usually be in association with a mental hospital. Even without an in-patient department they would be beneficial. He got chiefly cases of neurosis and the psycho-neuroses, but, contrary to some expressed opinions, he was sure some of these cases passed into genuine psychoses. Several cases, though not certifiable when they came in, became so later. He did not have certified patients in his ward as this embargo was essential to the character of the ward, and patients were told that as long as they were there they would not be certified, and they would not be associating with such patients. Last year he had as in-patients five men and 20 women; four of the men and 14 of the women recovered. Of the remainder, three were removed by friends at his request, the others being discharged, either relieved or not improved. It was difficult to know how they bore up afterwards as he had no system of liberation on trial as had the mental hospitals. Not one of the patients passed from him straight to a mental hospital. He occasionally received into his ward cases which had developed mental trouble in the general wards of the hospital. Five female nurses composed the nursing staff of the clinic; all were mental nurses, and one or two had also had general hospital experience.

A further sitting of the Commission took place on June 22nd, when the chair was occupied by Mr. N. Micklem, K.C.

Evidence from the Lady Chichester Hospital.

Lady Chichester and Dr. Helen Boyle attended and submitted evidence concerning the establishment at Hove which bears Lady Chichester's name, and which receives and treats women and children who are suffering from early mental disorder. Dr. Boyle is the senior physician at the hospital. Established in 1905, it is claimed to be the first attempt to deal in this way with early and "border-land" cases, the only parallel effort in the kingdom at that date being Dr. Carswell's in the Poor-law wards at Glasgow. This Hove hospital has 39 beds and an out-patient department, and it is maintained purely by voluntary effort, with no large benefactions. The conditions treated there were neurasthenia, organic nerve diseases, physical disabilities, early psychoses, and psycho-neuroses. Dr. Boyle explained that by early cases she meant patients whose trouble was at the time such as did not suggest any question of certification. She was not referring to cases which had recently become certifiable. The average cost of maintenance was only £1 19*s.* 7*d.* per week per in-patient, the low figure being due to the exercise of strict economy and the fact that a number of the patients were able to take a rota of duty.

Lady Chichester said the hospital was not free of debt, but current expenses were met year by year.

Dr. Boyle said the hospital kept full and there was always a long waiting-list. There was no geographical limitation in regard to applicants; indeed, patients had been there from Nigeria, Egypt, Scotland, and from London hospitals, as the latter had no beds for this class of case. One case of attempted suicide, the woman's impulse having probably been due to long-continued monotonous work in solitude, was sent from St. Thomas's Hospital, and was treated there with very beneficial results. In three months her weight increased 2 st. 4 lb.; she had now been working for two years in Brighton and was apparently fully restored. Lady Chichester remarked that a large part of the work of the hospital was done among harassed and over-wrought mothers, also a number of widows. Dr. Boyle said the hospital did not take cases which had been treated in mental hospitals, as these were supposed to be dealt with by an after-care association. It had, however, an out-patient department where ex-patients who felt they had some slight recurrence could come and talk over their symptoms. If a long time had intervened, cases might be readmitted as in-patients. She thought there should be some such institution at every considerable centre, and if possible, it was well to have it in association with the general hospital. When the Royal Sussex Hospital was approached with this view in 1905 the idea was too new. Laboratory investigations for the Lady Chichester Hospital was now done in the laboratory of the county hospital.

Dr. Boyle said she had visited and studied mental institutions in France, Germany, Austria, Canada, and Belgium, and everywhere the view was held that if early cases of mental disorder could be treated, many of them could thus be prevented from becoming certifiable at all. When the Hove establishment was started the Continent and America were well in advance in this matter, but to-day the disparity had been largely remedied. Her chief criticism of the continental clinics was that they took some cases which were too advanced so that they had locked doors, and this interference with the patient's liberty did much to neutralise their great distinguishing feature as compared with the asylum. She gave some instances of juvenile cases treated with an indication of the lines followed. Sometimes cases were taken in on the recommendation of their doctor, but sometimes the latter's description of the case proved to be inaccurate and misleading. Old patients were made welcome at a weekly "club night," and the witness hoped to see this social side developed much further.

Dr. Boyle was not enamoured of the idea of a provisional certificate, as the public would not be likely to regard it as very different from the ordinary one. If the mental hospitals did not receive acute recoverable cases, Dr. Boyle thought those institutions would become terrible places of despair, and good medical officers would be very unlikely to be attracted to the work in them. In a series of 23 acute cases, only three became well in three months.

Lady Chichester said that one acute case in the hospital would do a great deal of harm and would shake the belief of the public in its character. The average stay of patients in this hospital was about two months.

Dr. Boyle said she was not obsessed by psychotherapeutic measures in treatment, as many of the disorders were due to physical exhaustion and defects, and the aim was then to remedy these. If there were more such clinics people would see that there were various mentalities, and what they led to.

Asked by Sir Humphry Rolleston why cases of disseminated sclerosis were taken into this hospital, Dr. Boyle replied that she strongly favoured regarding the nervous system as a whole, and not making specialities of separate sections of it.

Dr. Boyle pleaded for greater freedom in these matters, for both doctor and patient. The doctor should be free to treat a willing patient whenever he thought it desirable or possible, and the patient should be at liberty to go for treatment where he wished or where the doctor might send him. She also favoured an unlimited number of licensed houses or private houses where patients could be treated; competition would keep up the standard of efficiency. At present it was very difficult, and a long time was necessary to effect transfer of a patient from a mental hospital he did not like to another.

THE MAUDSLEY HOSPITAL.

Dr. Edward Mapother, the medical superintendent of this institution, attended to give evidence as an individual who had had a good deal of experience of mental hospital administration. Mr. Macmillan, who now took the chair, mentioned that the Commission had recently visited the institution and inspected its research, teaching, and voluntary treatment departments. Dr. Mapother said he thought there should be a better adaptation of the legal processes to the attitude of the patient towards treatment. For instance, he would make treatment a means of avoiding certification. He also wished to see provision made for specialised types of institution which would deal in a separate way with recoverable cases and with chronic ones; also separately with patients who were objectionable and those who were quiet. He further wished to see an extension of the provisions for teaching and research. Certifiable patients included those able to coöperate in their own treatment, those who were passive in this respect, and thirdly, those who actively resisted efforts at treating them.

Clinics.—To the usefulness of clinics he thought there was a definite limit; in some cases they could not be regarded as substitutes for the mental hospital. The Maudsley did not receive certifiable patients; all who were there could have their discharge on 24 hours' notice. Three-fourths of those patients came via an out-patient department of a hospital. Some came on the recommendation of a mental specialist. More cases, though still willing and recoverable, were taken at the Maudsley Hospital than at Chichester House. Non-volitional cases should, he thought, be dealt with in clinics so long as they were not a nuisance to others. There were many recoverable cases among these.

Observation Hospitals.—Dr. Mapother thought fresh recoverable cases not suitable for clinics should receive their first attention at observation hospitals. A further reform he wished to see was that patients who had not reached the certifiable stage should be allowed to be private voluntary boarders, they being subject to similar supervision and visitation to that exercised in the case of certified patients. Contentment of patients would be arrived at if each institution had its own type of patient. At present, certainly in the gardens, refractory and quiet patients were in association. He favoured the employment of female nurses for male wards. In conclusion, he said he would like to see the accommodation at the Maudsley Hospital increased, and thought it would be a great advantage to have similar institutions in the chief centres of population.

MANCHESTER SANATORIUM FOR CONSUMPTIVES.—The Manchester Public Health Committee has received provisional sanction from the Ministry of Health to its scheme for extending the Abergele Sanatorium for Consumptives. The total cost of the scheme will be about £300,000, and it is proposed that ultimately the total number of beds will be increased to 540. It is proposed to put in hand at once an instalment to provide 210 beds at a cost of £183,768. The Ministry will make a grant of £180 per bed towards the cost, and contribute 50 per cent. towards the maintenance charges, including loan, interest, and repayment. This will be the largest sanatorium scheme undertaken in this country since the war.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The eighty-fourth annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held from Monday, July 6th, to Friday, the 10th, under the presidency of Sir Frederick Mott, at the University Buildings, Edmund-street, Birmingham. On Tuesday the 7th, at 11.30 A.M., a lantern demonstration will be given by Dr. David Orr on the Sympathetic Endocrine System, and the presidential address will be delivered by Sir Frederick Mott at 3 P.M. On Wednesday, the 8th, at 10.30 A.M., Dr. G. A. Auden will read a paper entitled Encephalitis Lethargica and its Psychological Implications, and a lantern-slide demonstration of the Lesions of Lethargic Encephalitis will be given by Sir Frederick Mott. At 7.15 for 7.30 P.M., the annual dinner of the Association will be held at the Grand Hotel, Colmore-row, Birmingham. On Thursday, the 9th, at 10.30 A.M., Dr. Graves will read a paper entitled Incidence of Chronic Sepsis in Mental Disease, and Dr. Pickworth will read a paper on the Iodine Content of Thyroid Glands. On Friday, the 10th, at 10 A.M., Dr. A. M. McCutcheon will read a paper entitled The Institutional Treatment of Mental Deficiency, with Special Reference to Occupational Training. At 11 A.M. Dr. W. A. Potts will read a paper on Delinquency, followed by Dr. Hamblin Smith on The Psychopathic Personality. A pleasant series of excursions and visits to places of interest in the neighbourhood has been arranged. The full programme may be obtained from Dr. R. Worth, hon. general secretary, Springfield Mental Hospital, Tooting, London, S.W.

"Audi alteram partem."

SICKNESS AND ACCIDENT INSURANCE.

To the Editor of The Lancet.

Sir,—From applications which have been received by the Medical Sickness, Annuity and Life Assurance Society Limited, 300, High Holborn, W.C., it appears that a number of medical men are unfortunately involved in the failure of the Profits and Income Insurance Company. The directors of the Medical Sickness Society (which was formed in 1884 by the late Mr. Ernest Hart on mutual lines solely for the medical and dental professions) have carefully considered in what way they could best assist their colleagues in their present difficulty, and are prepared to give consideration to any applications which may be made to them.

Inasmuch as the sickness premiums charged by the Profits and Income were considerably higher than those charged by this Society, policy-holders in many cases can obtain the same benefits from this Society as those for which they insured in the Profits and Income several years ago without paying increased premiums. Naturally, such applicants will now be desirous of ascertaining the financial position of any society or company in which they may desire to insure so that they may be confident that their claims will be met.

So far as the Medical Sickness Society is concerned I would, with your permission, refer them to the advertisement page in this issue of The Lancet, from which they will see that separate funds exist for life assurance and for sickness and accident invested in sound securities properly vouched for.

Your obedient servant,

Francis J. Allan,

Chairman, Medical Sickness, Annuity and Life Assurance Society Limited.

June 22nd, 1925.

THE PROBLEM OF MALIGNANCY.

To the Editor of The Lancet.

Sir,—Dr. A. E. Barclay is no dreamer; he has always been a thoughtful worker and his conclusions carry weight. He is convinced (vide The Lancet, June 20th) that in cancer there is an unknown factor, *x*, which he believes is a blood change—possibly biochemical. *X* determines the onset of local cell-overgrowth—i.e., tumour. So long as this blood change *x* exists, no cure is possible by operation or radiation, although in some cases local tumours may be removed by one or both means. If the blood change *x* clears up—as it may—then the patient can be cured provided the local cancer is removed by operation or by radiation. Clearly Dr. Barclay is right in declaring it a waste of time to look down a microscope for the cause of cancer. Search must be made for the underlying blood change (if such there be). I should like to take matters a step farther, for I believe that the *x* he is looking for is not altogether unknown; it is, in fact, the toxæmia of stasis. I see many cases of cancer, both for diagnosis and treatment, and I can state positively that each case, whether early or advanced, shows evidences of severe stasis. This statement might go unchallenged were it not that the conditions of our civilisation have led us so far from Nature's ways that toxic tissues are the rule, and healthy tissues the exception. Toxæmia is so general that many accept it as the normal state! But toxic tissues fall a ready prey to disease. Dr. Barclay quotes a case in which a cancerous breast has been removed and later a cancer has appeared in the other breast in the upper and outer quadrant. Stasis explains this; the breasts in stasis are nodular (chronic mastitis due to toxæmia); the nodules are most pronounced in the upper and outer quadrants. If the stasis is cured by treatment the nodules clear up; the breasts become smooth. If the stasis is allowed to go on the breasts may become cystic or cancerous; often first cystic, then cancerous. So, too, in the toxic stomach a chronic ulcer or chronic catarrh of the mucous membrane may pass over into cancer. In the toxic colon chronic catarrh of the mucous membrane with infiltration of the submucous tissue (colitis) leads to surface erosion and eventually to cancer. And so with other organs. Hence I can support Dr. Barclay in postulating a general devitalising process, but whereas he modestly names it *x*, I would bestow upon it the more definite and explanatory title "the toxæmia of stasis." To call it *x* is not helpful, whereas to call it "stasis" is immensely helpful, for it leads to efficient treatment and, I believe, goes a long way toward the prevention of cancer.

I am, Sir, yours faithfully,

Alfred C. Jordan.

Upper Wimpole-street, W., June 20th, 1925.

RECENT RESEARCH INTO SCARLET FEVER.

To the Editor of The Lancet.

Sir,—The editorial article on recent research into scarlet fever in your issue of April 11th interested me greatly. The impression which many readers who are not in close touch with this new study of the serum therapy of the disease will derive from the concluding paragraph, will, I fear, discourage early treatment of serious cases. This seems unfortunate, to say the least, in view of the fact that every important laboratory in this country (U.S.A.) which has seriously undertaken the study of scarlet fever by these new methods has, in the main, confirmed the observations of the Drs. Gladys and George Dick in Chicago, and Dr. Alphonse R. Dochez in New York City, and also many of their conclusions relating to serum therapy.

The evidence of the ætiological relationship of the *Streptococcus hæmolyticus* to scarlet fever is presented at length, but the editorial treats very briefly and inadequately important observations on the treatment of the disease with serum. It is possibly not yet time to undertake with profit a discussion of the various studies that have been made on the relation of the hæmolytic streptococcus to scarlet fever. The new methods of research undoubtedly offer unusual opportunities for testing the different strains and the relationship of their toxins by toxin-antitoxin neutralisation. The work of Miss Kirkbride and Miss Wheeler in this laboratory is bringing to light certain facts the significance of which will be more apparent later. The results of the practical application of serum therapy in scarlet fever, however, cannot be ignored or dismissed briefly. The clinical reports of several independent investigators are now available, and the results uniformly indicate definite therapeutic action in the treatment of the disease during the early stages of the rash—fall in temperature, disappearance of the rash, marked improvement in the symptoms—in short, what might be termed a true crisis, suggesting very strikingly that the toxin is neutralised, as it is in the treatment of diphtheria, with antitoxin.

Blake has recently reported extremely important observations on the mechanism of the action of the serum in the course of scarlet fever infection which are confirmed by clinical experience. His point of view will afford a very sound basis for the study of the results of serum therapy as they accumulate. Moreover, his observations on streptococcus infec ion in scarlet fever, in principle, parallel the conclusions of the experimental studies of pneumococcus infection and the action of immune serum which I have reported from time to time since 1912—namely, that in pneumonia the disease is largely a toxæmia complicated by parasitic invasion, and that the immune serum acts in a manner similar to antitoxin in diphtheria, neutralising the toxic substances. After all, the streptococci and pneumococci are so closely related that the study of their infectious processes should be very closely correlated. The longer we study the action of antipneumococcus serum in pneumonia and antistreptococcus serum in scarlet fever the more apparent will become the antitoxic action of these serums, the prognosis depending upon the character of the parasitic invasion of the incitant. In pneumonia, however, the parasitic invasion takes place immediately, whereas in scarlet fever, according to Blake's observations, it is preceded by a period of toxæmia which permits of complete and immediate neutralisation by the introduction of the serum. Such treatment may serve to prevent subsequent parasitic invasion and the development of septic complications which, once established, may not yield so readily to serum treatment. It is obviously of the utmost importance in the treatment of the disease that the anti-streptococcus serums which are now being distributed by a number of laboratories should possess the highest degree of potency.

"Scarlet fever streptococcus antitoxin" is listed among the new and non-official remedies in the *Journal of the American Medical Association*, May 2nd, 1925. Two different serums are described: one prepared by immunisation with the soluble toxin or filtrates of the hæmolytic streptococcus—standard of potency "each c.cm. neutralises at least 1000 skin test doses of scarlet fever toxin"; the other, by immunisation with living streptococci developing in the tissues—standard of potency "each c.cm. neutralises at least 10,000 skin test doses of scarlet fever toxin."

In the light of our present knowledge, there is no evidence that the serums differ materially in their action, which is similar to that of antitoxin. However, the potency of the serum in neutralising the skin test doses is of the utmost importance. During the past year we have been able to obtain serum of the highest potency by the method of Dochez.

I am, Sir, yours faithfully,

A. WADSWORTH,
Director, Department of Health,
Albany, N.Y.

THE PENSIONABLE AGE.

To the Editor of THE LANCET.

SIR,—In the annotation upon the pensionable age in your issue of May 30th last it is pointed out that heavy manual labour tends to shorten life, especially if indulged in after the age of 40. Raymond Pearl's opinion is quoted that all living organisms are like machines that can only transform a definite amount of energy and then die. As you put it, "the duration of life of an animal stands in inverse relation to the total amount of its metabolic activity." On reference to Dr. Pearl's book on the "Biology of Death" one finds that he quotes Prof. Max Rubner's view that all living organisms can only transform a limited amount of energy and that this is about the same for all and amounts to a mean of 191,600 calories per kilo. of body-weight.

According to this view a man comes into the world with a definite store of potential energy and when this is spent he goes out again, unless, indeed, death comes earlier from some intercurrent cause. This is an interesting theory and may be true, but surely there is another side to the question. One can imagine an elderly hypochrondriac calculating the total potential energy that heredity has bestowed upon him and coming to the conclusion that he must husband the little that he has left and hence must keep still and thus save what remains, like the poor miser with only a few coins left in his stocking. Thus being deprived of the exercise that in so many ways will help the proper functioning of his organs he may die sooner than he need, not because his energy is exhausted, but from some toxæmia or intercurrent infection, which gentle exercise might have averted.

Everyone will admit that hard physical exertion is bad for a man after middle life and will probably hasten his end, usually by damage to the circulatory apparatus, but on the other hand want of exercise also has a sting in its tail. One would like to see the powerful influence of THE LANCET urging the value of gentle exercise as well as warning against the dangers of hard physical exertion in people of mature years.

I am, Sir, yours faithfully,

Toronto, Canada, June 11th, 1925. R. D. RUDOLF.

THE PERIODICITY OF CHOLERA.

To the Editor of THE LANCET.

SIR,—Sanitary work in India is of so variable and urgent a character that ordinarily it is impossible for those responsible for its administration to spare time to acquaint themselves with schemes and themes of their predecessors; if they deal effectively with the present and immediate future they well fulfil their duty. Major A. J. H. Russell, I.M.S., in his paper on the above subject in your issue of June 13th, has proved himself no exception to this dictum. He has found that "very little information of value has been recorded in connexion with the epidemiological features of cholera." Hence, he proceeded to examine statistics for a period of 25 years of cholera deaths in the Madras Presidency applied to "groups of districts according to the periods in which these districts were affected by the different monsoons." This was the method employed by one of his predecessors in office in 1894, and formed the subject of a paper[1] read before the first Indian Medical Congress. This was illustrated by a diagram founded on the figures of a decade; it inhibited monthly periodicity so markedly as, in after years, to justify it being termed the "Madras Cholera Clock." In the paper certain deductions were offered as to the various factors concerned. These are not unreasonable when considered in the light of more recent work showing the variability of the cholera microbe, the existence of carriers, and the epidemiological data recorded by such authorities as D. D. Cunningham, Cornish, Greig, Aldo Castellani, Simpson, Tamezo Kebeshima, Paul Clements, Salvador Rosario, Trenkmann, and Pettenkoffer (vide Sanitation No., Tropical Diseases Bulletin, 1919, vol. xiv., No. 1, pp. 13–17).

In pursuing this method of inquiry, Major Russell claims he has discovered a six-yearly periodicity in the Madras Presidency, and thus has been enabled to prevent "waste of effort in unnecessary directions at unnecessary times." He further notifies his intention of verifying this possibility in the rest of India. For differentiating the numerous factors concerned throughout so vast an area, he has set before himself no mean task, and epidemiologists will wish him all success; but, so far as the Madras Presidency is concerned, I suggest he has already at his disposal information of the nature he desires in the "Madras Cholera Clock." At p. 14 of the bulletin above referred to, he will find the writer of the note on the subjects states, "later observations showed him that if cholera were introduced into a district in other than the period following its chief monsoon, it would fizzle out"; in other words, suppression can confidently be hoped for by less effort than under the opposite condition. I am, Sir, yours faithfully,

W. G. KING,
Colonel, I.M.S. (Ret.).

Hendon, N.W., June 22nd, 1925.

SALINE DRINK IN INDUSTRIAL FATIGUE.

To the Editor of THE LANCET.

SIR,—The question of fatigue in industry, especially amongst those engaged in heavy and laborious work carried on in a high atmospheric temperature—e.g., stokers and foundry-men, &c.—is important from several points of view. Health, efficiency, and output are essential factors, both from the worker's as well as the employer's standpoint, and various methods have been devised to overcome the factor of fatigue. Ventilation, humidity, rest intervals, and motion study have been carefully studied by progressive firms, so as to eliminate, so far as possible, losses in labour efficiency, an important factor in industry. Whatever the actual cause of fatigue may be, whether it be due to the formation of lactic acid and carbon dioxide, which rapidly accumulates in the muscles, and later in the blood-stream, or whether this condition may be contributed to by the exhaustion of one or more of the endocrine glands, or both causes combined, the fact remains that its effect upon individual workers is very marked, resulting maybe in cramp of the abdomen and exhaustion. This condition naturally increases the sick-rate amongst the personnel.

---

[1] The Seasonal Prevalence of Cholera in the Madras Presidency Embodied in the Transactions of the First Indian Medical Congress, 1894.

As the result of an experiment made some few months ago, which proved very successful, I introduced a "saline drink" for the stokers employed in the retort houses of the various stations of the South Metropolitan Gas Company. The composition of this drink is as follows: 120 g. potassium chloride, 180 g. sodium chloride per litre of water; 2·5 litres of this stock solution added to 213·3 litres (47 gallons) of water. The result has impressed me as well as the engineers in charge. Since this drink has been introduced, cramp has been eliminated and a greater sense of well-being at the end of each shift has been obtained. The great majority of the men will have no other drink. Incidentally, the sick-rate has been reduced. "Salt" is used in the tropics as a drink, no doubt for much the same reason, but I am not aware whether the combination with chloride of potassium has been employed. The effect of this drink appears to me to be due to the correction of the saline content of the blood which must be lowered by profuse perspiration, and if the worker drinks water only it must be lowered still further, thereby increasing fatigue.

I am, Sir, yours faithfully,
ROBERT J. W. OSWALD, O.B.E.,
Lieut.-Colonel, R.A.M.C.T.A. (R.); Chief Medical Officer, South Metropolitan Gas Co.
June 16th, 1925.

CURIOUS OBSERVATIONS ON THE TEETH.

To the Editor of THE LANCET.

SIR,—It seems only fair that I should write to thank you for the annotation on the reprint of Charles Allen's "Curious Observations on the Teeth," which appeared in your issue of April 11th. This notice attracted the attention of a member of the Royal Society of Medicine, who had a copy of the original book, dated 1687, which had been in the possession of his family for many years; he offered the book for sale and it has been acquired for the library of the British Dental Association. Librarians must frequently owe the acquisition of rare books to such notices as yours, and they act as reminders to those who possess these books and may have forgotten them or not have appreciated their scarcity and value. Our library is indeed indebted to you.

I am, Sir, yours faithfully,
LILIAN LINDSAY,
Hon. Librarian, British Dental Association.
Russell-square, London, W.C., June 16th, 1925.

INTERNATIONAL ASSOCIATION OF TEACHERS OF MEDICAL RADIOLOGY.

To the Editor of THE LANCET.

SIR,—As one looks round on the development of medicine throughout the world during the war, a number of surprising results may be noted. Specially striking is the development of the young science of radiology, whose second period of growth occurred when scientific thought was severely limited by frontiers. The roads along which this science advanced often diverged very widely. The most mutually contradictory opinions and measures were adopted and it is easy to understand how the desire grew up among radiologists first to know how far their science had advanced in other countries, and then to institute an exchange of experience and opinion on questions of research and instruction.

An international association of university lecturers in radiology, each specialising in some aspect of the work, seemed advisable. Such a proposal was made by a Vienna committee of lecturers and has found growing favour. Circulars were sent out, and the replies received up to the present from some 61 university lecturers in radiology have furnished valuable information. The 61 lecturers have formed a preliminary association, the several specialties of radiology being represented among them as follows: 11 are professors-in-ordinary of medical rontgenology, 6 are professors-in-ordinary of medical rontgenology, electrotherapy, and physiotherapy respectively, 12 are professors-extraordinary of medical rontgenology, 3 are professors-extraordinary of medical rontgenology, clinical medicine, and surgery respectively, 17 are associates of medical rontgenology, 2 are associates of medical rontgenology and clinical medicine or surgery, 3 are associates of rontgenology and radium science, 6 are associates of medical rontgenology and electrotherapy, also physiotherapy, and 1 is a reader in medical rontgenology.

University instruction has advanced on differing lines as the following table shows (it refers to those countries only from which we have been able to acquire detailed facts):—

Countries.	I. Number of university lecturers of (pure) medical radiology only.	II. Number of medical faculties or medical schools.	III. Relative proportions of I. to II.
Germany	5	23	0·2 (5 : 23)
Yugoslavia	1	2	0·5 (1 : 2)
Austria	12	3	4·0 (12 : 3)
Rumania	1	3	0·3 (1 : 3)
Russia	12	12	1·0 (12 : 12)
Switzerland	2	3	1·7 (2 : 3)
Czecho-Slovakia ..	4	3	1·3 (4 : 3)
Hungary	2	4	0·5 (2 : 4)

Italy, the United States of America, and other countries show very high indices, but the Association has not yet obtained full reports. The differences in the general appreciation of the radiology branch are not so marked—as with us its value has been recognised everywhere in a manner far exceeding early expectations.

Teachers of radiology who have not yet been reached by our circular or have not yet been induced to join our Association, are invited herewith to collaborate. The Association will also contain numerous consultative members.

The Association hopes to do useful work by publishing detailed information (list of members, &c.) in the *Fortschritte auf dem Gebiete der Röntgenstrahlen* and in the X ray archives of all languages. One of the objects of the Association is to promote coöperation among workers in radiology in all countries.

We are, Sir, yours faithfully,
HAUDEK,
KIENBÖCK,
HOLZKNECHT,
WEBER.
Executive Committee of the Association.
Langegasse 63 (parterre), Vienna VIII.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 13TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 97; scarlet fever, 1400; diphtheria, 773; enteric fever, 48; pneumonia, 829; puerperal fever, 44; cerebro-spinal fever, 6; acute poliomyelitis, 4; encephalitis lethargica, 59; trench fever, 1; dysentery, 4; ophthalmia neonatorum, 121. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 2 from the number for the preceding week. One case of small-pox was notified from the County of London (Bethnal Green).

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 61 from measles, 13 from scarlet fever, 78 from whooping-cough, 27 from diphtheria, and 36 from influenza. In London itself the deaths from influenza numbered 3, from whooping-cough 22, and from diphtheria 9.

Obituary.

ROBERT HENRY SCANES SPICER, M.D. LOND.,

CONSULTING SURGEON TO THE THROAT DEPARTMENT, ST. MARY'S HOSPITAL.

WE regret to announce the death of Dr. Scanes Spicer, which occurred on Thursday last, June 18th, at Graham-street, Chelsea, after prolonged illness.

Robert Henry Scanes Spicer was the son of an identically named father, also a physician, who practised at North Molton, Devonshire. He was born at North Molton in 1857 and received his medical education at St. Mary's Hospital, where he gained the first open science scholarship in 1877, and the scholarship in anatomy in 1881. At the University of London he graduated B.Sc. in 1877 with honours, and qualified in medicine in 1883 with honours in medicine, forensic medicine, and chemistry. He also obtained the gold medal in botany at the Society of Apothecaries. He served the usual resident appointments at St. Mary's Hospital, extended his studies in Vienna, and proceeded to the M.D. Lond. in 1885, at which date he was resident superintendent of the Fulham Infirmary. In 1888 he was appointed surgeon in charge of the throat department at St. Mary's Hospital, and lecturer on diseases of the throat and nose. These appointments he held for 20 years, when he was appointed consulting surgeon to the department.

Apart from this intimate association with St. Mary's Hospital, Dr. Scanes Spicer held many public appointments in connexion with his specialty. He was consulting surgeon to the Throat, Nose, and Ear School for the Blind at Leatherhead, honorary physician to the Royal Society of Musicians, and a Fellow of the French Société de Laryngologie. He was a vice-president of the old Laryngological Society, having been one of the original founders and the first honorary secretary. At the British Medical Association he was president of the Section for Nose, Throat, and Ear Disease in 1900.

He was a prolific author, contributing many articles upon his specialty to our own columns and those of the *British Medical Journal*, to the Transactions of the Clinical and Odontological Societies, and to the Proceedings of the Royal Society of Medicine. For the most part his papers were strictly confined to the surgery and pathology of the nose and throat. He was an early observer of the far-reaching consequences of post-nasal adenoids, and made practical communications on the surgery of the obstruction of the nose, on the treatment of chronic disease of the antrum, and the nasal relations of asthma. A large portion of his literary work was devoted to inquiry into the ætiological factors of malignant disease of the throat, and he made useful observations on the sites of origin in these growths, on their ætiological factors, and their treatment. He was also the originator of some ingenious theories as to the mechanics of respiration. An interesting paper on this subject, in relation to malignant disease, was published in THE LANCET in 1910, in which he described the topographical anatomy and the rigid resistances of the larynx and adjacent parts, as he considered them to bear on the sites of initiation and maximum development of cancer of the larynx. Dr. Scanes Spicer had retired from practice when the war broke out, but returned to work and served for four years under the Ministry of Pensions. A serious breakdown in health led to his retirement, and for the last five years of his life he was a complete invalid.

Dr. Scanes Spicer married Mary Wilhelmina, daughter of Mr. E. H. Huelin, by whom he had two sons and one daughter. Mrs. Spicer, who survives him, was her husband's devoted companion during a long and distressing illness, and we desire to record our sympathy with her and her family.

EDMOND JOSEPH McWEENEY,

M.D. DUB., F.R.C.P. IREL.,

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, UNIVERSITY COLLEGE, DUBLIN, NATIONAL UNIVERSITY OF IRELAND.

THE death occurred on June 20th of Prof. E. J. McWeeney, of Dublin. He suffered from a progressive nervous disease for several years past and death was not unexpected. A native of Dublin, Edmond McWeeney was educated at the Catholic University School in that city, and in the Collège de St. Bertin at St. Omer. He had a brilliant course in Arts in the Royal University of Ireland, ending with the university studentship in modern languages, which he won at the age of 21. Thereafter he could devote his full time to medicine, and he passed the final examinations with honours in 1887. He subsequently studied pathology in both Vienna and Berlin. In 1891 he was appointed professor of pathology and bacteriology in the Catholic University School of Medicine, and in 1908, when that school became the School of University College, he continued as professor and head of the department. He was also bacteriologist to the Local Government Board and pathologist to many of the city hospitals. He was elected a Fellow of the Royal College of Physicians of Ireland in 1905. Though the work entailed by his various offices would have fully occupied the time of a less energetic man, McWeeney found leisure to give to research. He kept in touch with work done in British and Continental laboratories, and with little assistance, and for many years with inadequate equipment, he performed an enormous amount of work and published frequently in the scientific journals. His class teaching was lucid and thorough, and his demonstrations to the Royal Academy of Medicine were perfect in their arrangement and clearness. Personally, he was a man of wide general culture, well read, much interested in botany as well as in his own subjects, and in his younger days a great walker. Seven or eight years ago, while in the full vigour of work, his health failed, and although he continued to perform some of the duties of his chair he was cut off from most of his activities. His eldest son, who had a distinguished career in the Air Force during the war, is now a member of the medical profession.

THE LATE DR. A. W. S. SMYTHE.—Arthur William Stafford Smythe, L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., died at Oxton, Birkenhead, on May 31st, at the age of 57. After studying in Dublin Mr. Smythe qualified L.R.C.P. & S. Edin. and L.R.F.P.S. Glasg. in 1891. Mr. Smythe was formerly medical officer on the West African medical staff in Southern Nigeria, and at the time of his death was in practice in Birkenhead, where he had resided for many years.

THE LATE DR. J. F. CARRUTHERS.—John Ferguson Carruthers, M.D. Edin., who died recently in his 67th year at Liphook, Hants, where he had lived in retirement for a few years, was the eldest son of Mr. Walter Carruthers, of Inverness, and a grandson of Robert Carruthers, LL.D. At 14 years of age he won a scholarship at Fettes College, Edinburgh. He was successful both in his work and in his games, winning prizes in sport at Fettes, and becoming a good cricketer. After an adventurous period in many parts of the world, he qualified M.B., C.M. at Edinburgh University in 1892 and gained the M.D. Edin. with honours in 1897. He practised for several years at Revelstoke in British Columbia, where he was medical officer of health. From 1903–5 he studied at Moorfields Eye Hospital, and then took up ophthalmic practice at St. Peter Port, Guernsey. Soon after the outbreak of the war he was appointed ophthalmic specialist at the Royal Herbert Hospital, Woolwich, where he remained till 1922. His duties in this post were extremely arduous, and it cannot be doubted that his unremitting work undermined his health. In 1922 he was appointed ophthalmic specialist at Bagdad in the R.A.F., with the rank of squadron-leader, but did not take up the post, and shortly afterwards retired. He married a daughter of Mr. W. Scott, of Edinburgh, who survives him.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the First Professional Examination for the Fellowship, held from June 9th to 18th, for which 115 candidates presented themselves, 40 candidates were approved and 75 were rejected. The following are the names and medical schools of the successful candidates :—

W. E. Barnie-Adshead, Birmingham ; W. J. H. M. Beattie, Cambridge and St. Bart.'s ; B. H. Burns, Cambridge and St. George's ; R. W. Butler, Cambridge and St. Thomas's ; T. L. Cleave, Bristol ; F. M. Collins, Cambridge and King's Coll. ; A. D. W. Cooke, St. Mary's ; D. W. Currie, Leeds ; D. A. Davies, Cardiff and St. Thomas's ; C. S. Dickson, Toronto and Middlesex ; A. A. Digges La Touche, Cambridge and Leeds ; J. Foster, London ; P. J. Ganner, Birmingham ; A. G. Harsant, London ; C. H. Hembrow, Melbourne and Middlesex ; H. Jackson, Middlesex ; J. H. F. Jayasuriya, Ceylon and Middlesex ; B. L. Jeaffreson, St. Bart.'s and St. Mary's ; Phyllis I. Kaufmann, Manchester and St. Mary's ; P. Kiely, Cork ; R. A. King, St. Mary's ; Winifred A. Ladds, London School of Medicine for Women ; P. Malpas, Liverpool ; J. N. Milloy, Glasgow and London ; F. J. Milward, Cambridge, St. Thomas's, and St. Mary's ; A. M. A. Moore, London ; E. G. Muir, Middlesex ; J. R. Peacock, Cambridge and St. Mary's ; G. G. Penman, Cambridge and St. Thomas's ; F. W. M. Pratt, Durham and St. Mary's ; L. N. Pyrah, Leeds ; M. P. Reddington, Otago and Middlesex ; O. W. Roberts, King's Coll. ; I. G. Sacks, Dublin and Middlesex ; J. N. Sankey, Birmingham ; H. Schneidin, Middlesex ; C. H. C. Searby, Melbourne ; J. E. Sykes, Liverpool ; Fanny M. Whittaker, St. Mary's and Charing Cross ; and H. S. T. Young, Cambridge and St. Mary's.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the undermentioned subjects :—

Surgery.—C. E. Hagenbach, St. George's Hospital ; E. J. Jones, Middlesex Hospital ; F. G. Martin, Charing Cross Hospital ; R. D. Mason, St. Mary's Hospital ; G. H. Weeber, Glasgow and Middlesex Hospital ; and J. W. Whitney, London Hospital.

Medicine.—I. H. Mackay, Sydney and London Hospital ; C. J. Rozario, St. Thomas's Hospital ; H. Winstanley, Liverpool ; and H. J. F. Wood, Guy's Hospital.

Forensic Medicine.—T. H. Harrison, Sheffield ; E. W. D. Long, London ; C. S. Netscher, St. Mary's Hospital ; and J. I. N. O'Sullivan, Dublin.

Midwifery.—T. H. Harrison, Sheffield ; A. H. Henson, Charing Cross Hospital ; and N. H. Ibrahim, Durham.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : I. H. Mackay, C. J. Rozario, and H. Winstanley.

INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.—The visit of the Assembly to this country terminated on June 21st, when the delegates left for Paris. We referred briefly last week to the visit paid to Belfast, where the Assembly were entertained in two detachments on June 11th and 12th respectively. Our Belfast correspondent sends us the following additional details. " A complimentary dinner to some of the leading delegates was held in the Medical Institute, Belfast, on the evening of June 13th. The chair was occupied by Dr. R. W. Livingstone, Vice-Chancellor of the University, and amongst the visitors present were Dr. Charles H. Mayo, President of the Assembly ; Dr. W. B. Peck, Organising Secretary; and Dr. Woods Hutchinson. The toast of The Visitors was proposed by the chairman and supported by Prof. Andrew Fullerton, Mr. A. B. Mitchell, and Dr. Alexander Dempsey. Dr. Mayo, Dr. Peck, and Dr. Woods Hutchinson suitably replied. In the course of the evening Dr. Mayo conferred the honorary membership of the Assembly upon Prof. Fullerton and Dr. Robert Marshall, who have borne the chief burden of the preparations for the reception of the American and Canadian visitors. Advantage was taken of the fine summer weather to explore some of the beauties of Northern Ireland, a party of 300 visiting the Giant's Causeway. The visit has left behind the happiest memories and will be long remembered with pleasure by all concerned. The intimate connexion of Northern Ireland with America and Canada was emphasised in many of the speeches made, and the existing ties have been cemented by the friendly and cordial intercourse of the last few days."

Glasgow.—On Monday, June 15th, the Assembly arrived in Glasgow from Ireland. A full and varied programme of lectures, clinics, and demonstrations had been prepared at the various infirmaries and hospitals of the city by the Glasgow Post-Graduate Medical Association, and these were well attended. On Tuesday the visitors were the guests of the University at a conversazione in the Bute Hall, where Sir Donald MacAlister, the Principal, accompanied by Lady MacAlister, formally welcomed the gathering. In the course of a short and witty address, he said : " In the name of my colleagues of this ancient medical school, one of the largest in the country, and in all modesty not the least famous, I bid you welcome to Scottish soil and Scottish hearts. In the name, too, of the General Council of Medical Education and Registration of the United Kingdom, of which for 20 years and more I have been President, I assure you of the hearty and brotherly welcome of the profession at large. A Latin poet speaks of the healer as *Opifer per orbem*, 'Helper the world over.' To-day the physician is more than ever hailed as a helpful fellow-citizen wherever he goes. For the time being we receive you as freemen of our ancient University. I call it ancient because it is older than Christopher Columbus, *just* older. There was still a Roman Emperor on the throne of Byzantium when it was founded. Our Faculty of Physicians and Surgeons was chartered before Lord de la Warr settled Virginia, or Champlain settled Quebec. So you see the United States and Canada are comparatively modern from our point of view. With all the reverence due to youth, we venerable seniors greet you and give you our blessing." Referring to Dr. Mayo, he said : " Dr. Mayo, I was unable to share as I would in the great and friendly reception which was offered you in London, both as the leader of this new crusade of Knights-Hospitallers and for your own and your brother's sake. I am proud and happy to receive you now in Glasgow, and to offer you the right hand of fellowship, fellowship international, fellowship professional, and fellowship of spirit and purpose. The motto of the Mayos is *E cruce salus ;* may your eastern crusade make for the health of the nations and the healing of their wounds." Dr. Mayo replied on behalf of the visitors, and in acknowledgment of the hospitality he bestowed on Principal MacAlister, Prof. Archibald Young, and Dr. James Carslaw, secretary of the Glasgow Post-Graduate Association, honorary membership of the American Assembly. Wednesday the 18th was spent in an excursion to Loch Lomond and the Trossachs, and in the evening the visitors were the guests of the corporation at a dinner in the City Chambers, when Mr. Montgomery, the Lord Provost, gave an address of welcome.

Edinburgh.—The visit to Edinburgh extended from Thursday, June 18th, to Saturday, the 20th. The time allowed was limited, in fact far too short for anything in the nature of systematic study of the medical schools, but great credit is due to Dr. J. D. Comrie for the intensive programme arranged by him both in the varied series of clinics and the social receptions and sight-seeing arrangements. The programme was opened by a reception in the McEwan Hall, followed by a graduation ceremony at which the honorary degree of Doctor of Laws was conferred upon Dr. Charles H. Mayo. Sir Alfred Ewing, Vice-Chancellor of the University, opened the proceedings by welcoming the visitors. Edinburgh, he said, was the nursery of medicine, and for that reason he wished them particularly to feel at home. Their visit was mainly, he imagined, to meet the teachers face to face and to profit by the electrical stimulus that came from contact not only with the methods but with the men. Following the graduation ceremony, activities were immediately transferred to the various medical departments and especially the Royal Infirmary, where a number of clinics were arranged for the two hours of the morning that remained; ten were given on the medical side and nine on the surgical, while separate arrangements were made for those interested in diseases of the eye, ear, nose, and throat. After an interval for lunch three demonstrations were held in theatres at which a series of physicians and surgeons presented cases and methods, amongst others, cases of fibromatosis of the stomach, plastic repair of face and limbs, while therapeutic problems were discussed by Prof. Gulland, Prof. Murray Lyon and others. In the evening the Lord Provost, magistrates, and council of the city held a reception in the Royal Botanic Garden, during which a lecture was given by Mr. R. M. Adam on life in the outer isles of the West of Scotland. On the following day, Friday, the 19th, a pathological demonstration was held in which the departments of surgery, midwifery, pathology, bacteriology, and diseases of the skin combined their exhibits to form an extensive collection of all departments of medicine, while early in the day a lecture was given by Mr. J. W. Dowden upon early active movement in fractures of the upper extremity. During the morning a number of cliniques and demonstrations were given as on the preceding day, at the Royal Hospital for Sick Children, the Royal Simson Maternity Hospital, and other institutions. In the afternoon a further series of theatre demonstrations was held. Later in the day the visitors had an opportunity for sight-seeing, and inspected the State apartments of Holyrood Palace, which had been opened by special permission. The visitors left for Newcastle on Friday night and Saturday morning after their flying visit. The opinion expressed by Dr. G. H. Beck, of Baltimore, as to the work in Edinburgh seems to be the general impression of the party. Dr. Beck spoke of the thoroughness of the Edinburgh surgeons and doctors and commented favourably on the type of practitioner in Edinburgh. He said that there was no undue haste on the part of doctors in the city to adopt novel methods, unless these had been proved to be of value.

Newcastle.—On Saturday, June 20th, some 85 members of the Assembly visited Newcastle and inspected the principal hospitals. The guests were welcomed at the Royal Victoria Infirmary by Lord Armstrong (chairman of the house committee), Sir Thomas Oliver, Dr. Thomas Beattie, Dr. A. M. Martin (chairman of the hon. medical and surgical staff), and Dr. R. A. Bolam Surgical operations were then witnessed, and the various departments were inspected, followed by a visit to the College of Medicine and the War Pensions Hospital. A civic luncheon was held in the Grand Assembly Rooms, where the guests were received by the Lord Mayor and the Sheriff. Dr. Mayo, replying to the toast of "Our Distinguished Guests," proposed by the Lord Mayor, said that in recognition of the beneficent work carried out by the Royal Victoria Infirmary, it had been resolved to make Lord Armstrong, Prof. Rutherford Morison, Dr. Beattie, Dr. Martin, and Mr. G. Grey Turner honorary members of the Inter-State Post-Graduate Assembly of America.

West London Medico-Chirurgical Society.—The annual general meeting of this society will be held at 5 o'clock on Friday, July 10th, at the West London Hospital, W. 14.

Society for the Study of Inebriety.—A meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, July 14th, at 4 P.M., when Dr. C. W. Saleeby will open a discussion on Sunlight and Alcohol.

Tuberculosis Society.—The annual meeting of this society will be held on Tuesday, July 7th, at Pritchard's Restaurant, 79, Oxford-street, London, W. The meeting will be preceded by a dinner at 5*s.* 6*d.* per head, and it is hoped that as many members as possible will attend. It is requested that those intending to be present should notify the Hon. Secretary, 138, Herbert-road, Woolwich, S.E. 18, as early as possible.

Epsom College.—The Council of Epsom College will shortly elect two girls to St. Anne's Home Scholarships of £48 a year. Candidates must be fully 7 years of age and not over 12, and must be necessitous orphan daughters of medical men who have been for not less than five years in independent practice in England or Wales. Application must be made on a form to be obtained from the Secretary, 49, Bedford-square, W.C. 1, by July 7th.

Powell *v.* Maybury.—The hearing of an action brought against Dr. Lysander Maybury, senr., of Southsea, by Mr. Percy John Powell, for alleged improper medical treatment and negligence, was concluded at the Hampshire Assizes on Saturday before Mr. Justice Shearman and a special jury. The jury awarded the plaintiff £1000 damages. We understand that an appeal has been lodged.

The Royal West Sussex Hospital.—Lord Woolavington, of Lavington Park, Sussex, has, in response to a letter from the secretary of this institution pointing out the urgent need of funds, forwarded a cheque for £1000. At the annual meeting of the governors in April a deficit of £1624 was reported on the year's working.

London Dermatological Society.—A meeting of this society was held at St. John's Hospital, London, on June 17th, when the annual oration of the society was delivered by Prof. Dubreuilh (Bordeaux) on Chronic Sunburn and Epithelioma of the Skin. (An abstract of this address appears on p. 1355 of this issue.) A vote of thanks to the orator was proposed by Dr. Knowsley Sibley and supported by Dr. J. L. Bunch and Dr. Prosser White. Prof. Dubreuilh replied. The annual general meeting was then held, when the following officers were elected for the ensuing session: Patron: The Earl of Chesterfield, K.G. President: Dr. William Griffith. Council: Ex officio, members of the staff of St. John's Hospital—Dr. W. Griffith, Dr. Knowsley Sibley, Dr. W. Fox, Dr. H. MacCormac, Dr. S. E. Dore, Dr. J. M. H. MacLeod, Dr. A. C. Roxburgh; and past-presidents of the society: Dr. A. T. Bremner, Dr. J. L. Bunch, and Dr. Prosser White; together with Dr. Knyvett Gordon, Dr. S. R. Kapoor, Dr. R. H. Rattray, Dr. R. H. Scovell, and Dr. D. Vinrace. Hon. Treasurer: Dr. Knowsley Sibley. Secretary: Miss M. Atkinson. Pathological Subcommittee: Dr. Griffith, Dr. Knyvett Gordon, and Dr. R. F. Fagan. The annual dinner of the society was held the same evening at the Trocadero Restaurant, Prof. Dubreuilh being the guest of the evening.

Sunlight Clinic for Hull Children.—In April, 1924, Hull established the first municipal clinic for the treatment of rickety children by artificial sunlight, and so great has been its success that it is to be greatly enlarged. At present only 20 children can be treated at once, and there is, naturally, a long waiting list.

Enlargement of St. Cross Hospital, Rugby.—Mrs. Arthur James, the president of this hospital, has undertaken the cost of enlarging it in memory of her late husband. St. Cross is a 100-bed hospital which has been doing the work of a much larger institution, and its resources will now be increased to from 125 to 130 beds. It is an approved hospital for the treatment of non-pulmonary tuberculosis and of venereal diseases.

Berlin: International Post-Graduate Courses. The following post-graduate courses, organised by the Faculty of Medicine of Berlin University, will be held in Berlin in October: (1) Special courses on all branches of medicine dealing especially with those subjects that are of present interest to the profession as a whole. These courses include practical work. (2) A series of lectures on internal medicine, with special reference to diagnosis and therapy in general practice. (3) Systematic review of the progress of medical science and technique. (4) Post-graduate course for oculists. Further details and a full programme of the courses may be obtained from the offices of the International Post-Graduate Courses, Kaiserin Friedrich-Haus für das ärztliche Fortbildungswesen, Luisenplatz 2–4, Berlin, N.W. 6.

Medical Golfing Society.—The annual summer meeting was held at Moor Park on June 11th. Over 90 members took part in a most successful tournament. The results were as follows, all the competitions being against bogey:—The Lancet Challenge Cup (scratch): H. D. Gillies, 3 up. Henry Morris Challenge Cup (handicap): J. O'Malley (6), all square. Milsom Rees Challenge Cup (scratch return in second class): H. P. Aubrey, 5 down. Class I.:—First prize, L. E. Barrington-Ward (9), all square. Second prize: L. Forest (8), L. Welply (8), G. Norman (10), A. H. Vassie (11), and J. Grace (7), tied at 1 down. Class II.:—First prize: G. F. Wilson (14), all square. Second prize: C. V. Mackay (11), 1 down. Best last nine holes: W. A. Rogerson (12), 1 down. Foursomes: G. P. Kennedy (8) and L. Welply tied with Arthur Evans (8) and S. G. Bonnalie (5).

Livingstone College Commemoration Day.—On June 10th Commemoration Day was held at Livingstone College, Leyton, London, E., Dr. Andrew Balfour in the chair. Dr. Tom Jays, the Principal, made a short statement as to the financial position of the College, showing that about £800 was needed in order to close the current financial year without a deficit. He showed that the need was for more students, as owing to the lessened numbers entering since the war, and also to much extra necessary expenditure, the financial burden was heavy. He spoke of the world-wide influence of Livingstone College, the students of which were now scattered in almost every part of the globe. Dr. Balfour said that what had impressed him extremely in his knowledge of the work of Livingstone College was the way in which the students were trained in persistency in their studies and work. "Persistence," he said, "is a great matter; it is needed as much in missionary labours as in medical work. In the mission field there is often great discouragement at the small signs of progress." He pointed out that in addition to learning something of medicine and surgery, the students also learned preventive work in hygiene as applied to tropical disease. "There is," he said, "a vast deal of common-sense in public work, and much can be done by following certain rules. It is a saner plan to keep folk well than to cure them when they have fallen ill, beside a saving of a vast amount of money." The Rev. H. Wakefield, a student of the Primitive Methodist Mission, Calabar, West Africa, said he had often wondered what would happen if old Livingstonians all the world over were to send their testimonies of what Livingstone College had done for them. It would not be a story of increased salaries, of promotion to the heads of departments, but a story of gigantic struggles against disease and squalor. It would be a great human document of combating death, of alleviating pain, of fighting with customs against disease, against those forces which make men miserable and unhappy. Mr. F. Kilbey, of the Friends' Foreign Mission, Central Provinces, India, a student of the first session, told of his 30 years' work in the field, and of the work he had been enabled to do through the knowledge he had gained. "I would advise every man and woman," he said, "who contemplates residence in India, to take such a course as Livingstone College offers, and I feel sure that anyone who avails himself of it will be able to give like assistance to the people as I have been able to give." Among those present were Sir George Makins, Dr. P. Manson-Bahr, Dr. Whitfield Guinness, Dr. J. H. Cook, Mrs. Batchelor Russell, and Miss Rachael Barclay.

Dudley Guest Hospital.—About £15,000 has been obtained by a bazaar and a direct appeal to clear off the debt on this hospital of 115 beds. The remarkable sum of £1164 was taken at the doors.

Tuberculosis Society of Scotland.—A meeting of this society will be held at the British Medical Association, "Scottish House," 6, Drumsheugh-gardens, Edinburgh, on Thursday, July 9th, at 4.30 P.M., when Prof. Holger Möllgaard and Prof. Knud Faber, Copenhagen, will give a lecture on the Sanocrysin (Gold) Treatment of Tuberculosis.

Civil Service Nursing Homes.—A committee has been appointed by the National Whitley Council to investigate the possibility of setting up nursing homes to provide medical and surgical treatment for members of the Civil Service. It is proposed that Civil servants who join the scheme should pay a small annual subscription, and since there are nearly 300,000 of them it is believed that a large income would be secured. It is suggested either that a nursing home should be purchased or that arrangements should be made with existing institutions.

Meanwood Mental Defective Colony, Leeds. This colony is to be enlarged at a cost of £70,000 with a view to trebling its scope and usefulness. At present there are 170 beds with a waiting list of 500. Patients are to be housed in separate pavilions, each containing from 40 to 55 patients. Including interest, sinking fund, and maintenance charges, and deducting 50 per cent. on approved outlay contributed by the Board of Control, the scheme will cost the Leeds ratepayers about £10,000 a year.

East-End Mothers' Lying-in Home.—A formal annual meeting, for the purpose of electing the committee and honorary officers, was held at the Home on June 17th, under the presidency of Dr. Owen Lankester. A resolution expressing confidence in the work of the Home and adopting the annual report and balance-sheet was passed. During the year an adjoining building already arranged with cubicles suitable for nurses and provided with lecture rooms was acquired, and an appeal is being made for £14,500 to put the work on a reasonable financial basis under the new conditions, which will enable between 20 and 30 additional patients to be taken. The report of Dr. W. H. F. Oxley, the hon. visiting medical officer, shows that in 1924, 999 mothers were delivered in the Home and 1119 on the district. There was no maternal death, no case requiring Cæsarean section, and no case of puerperal septicæmia or eclampsia. All complicated cases are dealt with in the Home. Four patients were transferred elsewhere; one had puerperal mania, one paralysis, later developing epileptic convulsions, one pernicious anæmia, and one ovarian tumour, which was operated on in the London Hospital. All four made a good recovery.

Fellowship of Medicine and Post-Graduate Medical Association.—On Friday, July 3rd, at 5.30 P.M., Sir John Thomson-Walker will lecture on Urinary Infections (see "Medical Diary").—The special courses to be given during July include one, for a fortnight, starting on July 6th, in Children's Diseases at the Queen Hospital for Children, when there will be demonstrations of surgical, medical, orthopædic, skin, and chest cases, with lectures and operations; and a special three weeks' course in Neurology at the West-End Hospital for Nervous Diseases—comprising lectures and demonstrations on selected cases—at 5 P.M. daily, beginning on July 27th.—Lasting for a fortnight and beginning on August 4th, there will be an intensive course in General Medicine, Surgery, and the Special Departments at the North-East London Post-Graduate College (Prince of Wales's General Hospital), when lectures and demonstrations on all branches of medicine and surgery will be given. The daily sessions will last from 10.30 A.M. to 5.30 P.M.—Starting on the same date, the All Saints' Hospital will give a month's course of instruction in Urology; there will be clinical demonstrations throughout the month, and a special lecture will be delivered on each Wednesday afternoon.—From August 24th to Sept. 5th, the Queen Mary's Hospital, Stratford, will hold an intensive course, when lectures and demonstrations will be given in Medicine, Surgery, and the Special Departments.—Copies of the syllabuses and the programme of the Fellowship of Medicine may be obtained from the Secretary at 1, Wimpole-street, London, W. 1.

International Congress of Nurses.—A congress convened by the International Council of Nurses is to be held in Helsingfors, Finland, under the presidency of Baroness Sophie Mannerheim, matron of the Surgical Hospital, Helsingfors, commencing July 20th. Representatives are expected from the United States of America, from Canada, and from the Dominions, with a total attendance of at least 1000. Members of the public and of the medical profession are admitted to the meetings

Royal Medical Benevolent Fund.—At the last meeting of the Committee 52 cases were considered and £573 voted to 39 applicants. The following is a summary of the new cases relieved :—

M.R.C.S. Eng., 1913, aged 35, who helped his father in practice until the father's death last year. Served in France, Salonica, and Egypt from 1914 to 1918. Discharged on account of dysentery and malaria. Disablement pay £126 per annum. Discharged himself from hospital but was taken suddenly ill and is now in lodgings in London, at a cost of £2 10*s.* per week. Emergency grant of £20 to help with debts contracted during this illness was paid. Case brought to the notice of the Fund by the Officers' Association.

Widow, aged 62, of M.R.C.S. Eng., 1873, who practised in London. Applicant divorced her husband in 1906, he married again and died in 1914. Since 1906 applicant has supported herself as a manageress in several posts. Suffers from severe varicose ulcers which obliged her to give up her posts. These illnesses exhausted her resources, and worry and anxiety brought on cerebral hæmorrhage on Feb. 15th of this year. Has recovered to the extent of getting about a little but could only take a very light post. At present without means and is dependent on some poor relations. Applicant has no children and no friends who can give any material assistance. Case brought up by Charity Organisation Society. Voted £26 in 12 instalments.

Daughter, aged 77, of M.R.C.S. Eng., 1839, who practised in London and died in 1872. Applicant and her sister kept a girls' school until too old to carry it on. She has an annuity of £67 and adds to this by teaching French and other languages to the extent of £10 last year. A boarder pays £1 a week and only 10*s.* during the holidays. Friends contributed £30, and her rent and rates come to £77 per annum. Applicant's sister was an annuitant of the Fund until her death last year. Voted £12 in 12 monthly instalments.

Widow, aged 59, of M.R.C.S. Eng., 1879, who practised in Kent, Yorkshire, and N. Wales and died in 1921. Applicant has supported herself by taking boarders, but she is compelled through ill-health to give this up. The three married sons allow her £1 10*s.* a week between them. The daughter, aged 30, is at home looking after the house. Income from boarders £96. Rent and rates about £48 per annum. Voted £18 in 12 monthly instalments.

Daughter, aged 29, of L.R.C.P. Edin., 1880, who practised in Lincolnshire and died in 1915. Applicant was left with her brother and sister to educate. She has struggled to do this by letting rooms and by clerical work. Her salary has been reduced to £2 a week and letting brought in £52. Rent and rates come to £78 per annum. Applicant asks for help for the fees which are owing for her brother, who is in his last term at school at Lincoln. Also for influence to get him a post in a bank. His ambition is to be a doctor or articled to a solicitor. She states that her sister also requires some work. Voted £20 and referred to the Guild for further inquiries.

Widow, aged 80, of M.R.C.S. Eng., 1898, who practised in West London and died in 1919. Applicant has been living on the capital left by her husband and has only £90 left. She is applying for the old age pension. Board-residence amounts to £2 2*s.* per week. Voted £26 in 12 monthly instalments.

Wife of M.B. who is at present in an asylum and has been for the last four and a quarter years. Applicant has only an income derived from a trust fund which amounts to about £27 per annum. A friend has given her £200, which is invested for the present. The husband's board has been reduced to £58 per annum and his sister defrays half of this amount. Son, aged 16, started in business in December as a junior clerk at £36 per annum. His travelling costs are 30*s.* a month and he has to pay for his lunches. Voted £18 in 12 monthly instalments.

Widow, aged 53, of M.R.C.S. Eng. who had a post at the Ministry of Pensions and died in March. Since October has been living on the bounty of friends. The friends think it is now time for the applicant to look for some work and help to keep herself. Has no income whatever, only a little pocket-money from a friend. Late husband was in receipt of £2 3*s.* 4*d.* a month from the Fund. Voted £12 in 12 monthly instalments.

Daughter, aged 69, of M.D. Edin., 1840, who practised in Sunderland and died in 1884. Applicant has managed to support herself although she is deaf and has been so since the age of 16. Has tried letting apartments but finds it does not pay. Only income £60 from the "Dull" Fund which she obtained in 1910. Rent and rates at present £77 per annum. Voted £12 in 12 monthly instalments.

Wife, aged 58, of L.R.C.S. Irel. who has chiefly taken locums. She is separated from her husband, who is a drug-taker and allows her nothing. Dependent on two daughters, whose incomes are really only sufficient for themselves. Voted £9 in 6 monthly instalments.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, 11, Chandos-street, Cavendish-square, London, W. 1.

INDIAN MEDICAL SERVICE:
ANNUAL DINNER.

NINETY-TWO officers of the Indian Medical Service —the same number as a year ago—sat down to the annual dinner at the Trocadero, London, on June 17th. Lieut.-Colonel A. W. Alcock, C.I.E., F.R.S., occupied the chair, and the other members present were as follows :—

Major-Generals : Sir R. H. Charles, G.C.V.O., K.C.S.I. ; Sir G. G. Giffard, K.C.I.E., C.S.I. ; G. F. A. Harris, C.S.I. ; R. Heard, C.I.E. ; Sir P. Hehir, K.C.I.E., C.B., C.M.G. ; H. Hendley, C.S.I. ; A. Hooton, C.I.E. ; J. B. Smith, C.B., C.I.E.

Air-Commodore : D. Munro, C.B., C.M.G.

Colonels : H. Ainsworth ; A. Cochrane ; J. Crimmin, V.C., C.B., C.I.E. ; A. A. Gibbs ; T. A. Granger, C.M.G. ; J. A. Hamilton, C.M.G. ; A. J. Macnab, C.B., C.M.G. ; E. L. Perry, D.S.O. ; J. J. Pratt ; H. Austen Smith, C.I.E. ; C. N. C. Wimberley, C.M.G.

Lieut.-Colonels : W. G. P. Alpin, O.B.E. ; J. Anderson, C.I.E. ; R. F. Baird ; G. T. Birdwood ; E. W. C. Bradfield, O.B.E. ; J. T. Calvert, C.I.E. ; D. G. Crawford ; J. M. Crawford, O.B.E. ; C. D. Dawes ; C. L. Dunn ; A. M. Fleming ; A. T. Gage, C.I.E. ; E. V. Hugo, C.M.G. ; T. Hunter, C.I.E. ; C. H. James, C.I.E. ; S. P. James ; J. G. Jordan ; R. S. Kennedy, D.S.O., M.C. ; J. C. G. Kunhardt ; Clayton Lane ; W. B. Lane, C.I.E., C.B.E. ; W. H. Leonard ; R. McCarrison, C.I.E. ; F. O. N. Mell, C.I.E. ; A. Miller ; T. R. Mulroney ; J. G. P. Murray ; F. O'Kinealy, C.I.E., C.V.O. ; N. Rainier ; C. H. Reinhold ; Sir J. R. Roberts, C.I.E. ; Sir L. Rogers, C.I.E., F.R.S. ; E. R. Rost, O.B.E. ; H. E. Stanger-Leathes ; S. Browning Smith, C.M.G. ; R. Steen ; Ashton Street ; W. A. Sykes, D.S.O. ; C. Thomson ; W. H. Thornhill ; J. H. Tull Walsh ; H. J. Walton ; C. E. Williams ; Ellacott L. Ward ; D. P. Warliker ; N. M. Wilson, O.B.E. ; H. G. L. Wortabet ; A. C. Younan.

Majors ; H. L. Batra ; O. A. R. Berkeley-Hill ; Sir T. J. Carey-Evans, M.C. ; R. A. Chambers, O.B.E. ; D. Coutts, M.B.E. ; G. F. Graham ; A. E. Grisewood ; R. Knowles ; B. E. M. Newland ; P. M. Rennie ; C. J. Stocker, M.C.

Captains : P. M. N. Antia ; H. L. Barker ; S. D. Billimoria ; Leo Blake ; H. Horan Brown ; H. R. Cursetji ; W. P. Hogg, M.C. ; N. S. Jatar, D.S.O. ; V. R. Mirajkar ; C. S. V. Ramanan ; W. C. Spackman ; P. Vieyra.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Budget Concession to Medical Men.

A CONCESSION of some importance to medical men was granted by the Chancellor of the Exchequer during the Committee stage of the Finance Bill as the result of an amendment moved by Lieut.-Colonel FREMANTLE. It provides that the allowance of income-tax reductions in respect of the wear and tear of machinery and plant and in respect of expenses incurred in replacing obsolete machinery or plant shall in future apply to a profession, employment, vocation, or office, as well as a trade. Under this new clause a doctor's motor-car, if used in the course of his practice, will count as machinery and plant, and it will therefore be possible for a medical man to claim a deduction for the wear and tear of his car caused by its use for professional purposes. The exact amount of the deduction will be subject to arrangement between the taxpayer and the income-tax authorities.

Nursing Homes (Registration) Bill.

On June 19th Mr. HURST moved the second reading of the Nursing Homes (Registration) Bill, the principle of which, he said, was agreed to by all parties in the House. Captain ELLIOT (Under Secretary for Health, Scotland) said it was not possible to consent to the second reading of the Bill at that stage, but if the hon. Member would withdraw it he could make a promise on behalf of the Government to refer the subject of nursing homes to a Select Committee for inquiry. The Bill, on this undertaking, was withdrawn.

Public Health Bill.

On consideration of the Public Health Bill, as amended in Standing Committee, on June 19th, Mr. H. WILLIAMS moved a new clause which, he said, had been put down on the recommendation of the Royal Sanitary Institute. Its object was to isolate food intended for sale from causes of contamination, and gave the medical officer, sanitary inspector, and any other officer of the local authority the power to inspect a room in which food was kept in order to see that the provisions of the clause were being complied with. The clause was read a second time and added to the Bill. The Bill, which is a measure consolidating a number of powers conferred on certain local authorities by private legislation and making them applicable to the whole country, was read a third time.

HOUSE OF COMMONS.

THURSDAY, JUNE 18TH.

Medical Referees and Letters to the Press.

Mr. JOHN BAKER asked the Home Secretary whether his attention had been drawn to a letter from a medical referee under the Workmen's Compensation Acts which appeared in the *Morning Post* of June 5th ; whether officers who were paid by the Ministry were allowed to express, in the public press, opinions contrary to the Acts which they were administering ; and whether medical referees were governed by the ordinary rules governing the Civil Service, which prohibited officials from communicating to the press on matters connected with their employment. —Sir W. JOYNSON-HICKS replied : I have seen the letter. Medical referees are not Civil servants, but private practitioners paid by fees for their services in connexion with applications for compensation. No rules have been laid down as to communications by them to the press on subjects connected with the Acts, but I am sure that the referees generally appreciate the responsibility in this matter entailed by their special position.

Powers of Medical Referees.

Mr. JOHN BAKER asked the Home Secretary whether his attention had been drawn to a reserved judgment by his Honour Judge Ruegg, K.C., at Stoke County Court on June 3rd regarding the powers under the Workmen's Compensation Act of a medical referee ; whether, seeing that it had been decided that a medical referee under the Act had authority to decide not only whether or no the man was suffering from the disability, but also whether or no he was fit for employment, he would consider the desirability of taking such action as might be necessary to limit the powers of the medical referee merely to deciding the question of the disability from which a man was suffering ; and whether he would consider granting compensation to a man (F. B.) who was, at the time of his examination by the certifying surgeon, suffering from miner's nystagmus and was thereby disabled from obtaining employment.—Sir W. JOYNSON-HICKS replied : This case was one under the Industrial Diseases Section of the Act of 1906, and by that section the question whether a worker is disabled by an industrial disease from earning full wages at his ordinary work has to be determined by the certifying surgeon in the first instance and, on appeal, by the medical referee. The suggestion in the question would involve a complete change in the present system which has been in force for nearly 20 years and has, on the whole, worked well, and would apparently leave the question whether or not the worker was disabled by his disease to be fought out in the courts. I do not consider such a change is either necessary or desirable. In reply to the last part of the question, I have no power under the Act to grant compensation. This can only be done by the courts.

Ambulances and London Street Accidents.

Colonel DAY asked the Home Secretary if he was aware that a person meeting with an accident in the streets of London, however serious his condition might be, was compelled to await the arrival of an official ambulance before he could be removed ; and would he examine these regulations with a view to the betterment of these conditions.—Sir W. JOYNSON-HICKS replied : I know of no such regulations. The instructions to the police are to give the sufferer the first consideration, and if an ambulance is not readily available to employ a cab or other vehicle if the patient's condition appears to justify it. It must however, be borne in mind that it is dangerous to move cases of many common types of injury in any vehicle but an ambulance. If the hon. Member will give me an instance where it was desirable to move a patient quickly and a refusal was given I will look into it.

Medical Men and Unattended Motor-cars.

Mr. NEIL MACLEAN asked the Home Secretary whether he was aware that regulations existed which rendered medical men liable to prosecution if they left a motor-car unattended in the street ; and whether he proposed to issue a regulation exempting them when these circumstances arose in the course of their professional duties.—Sir W. JOYNSON-HICKS replied : Medical practitioners are not exempt from the ordinary law as to driving offences, and I understand that the Minister of Transport does not think it practicable to make exceptions to the existing law or regulations in favour of any particular class of persons. The police, of course, exercise discretion in regard to prosecuting for obstruction when it is caused by a doctor's attendance on a patient.

Mr. Maclean: Is the right hon. gentleman not aware that practitioners who are visiting sick patients have been summoned and that it is only owing to the good sense of the magistrate—even after the constable had explained the case—that they were saved from a conviction? Will the right hon. gentleman make some regulation which will enable a medical practitioner to have the particular privilege when visiting sick people of leaving his car unattended?

Sir W. Joynson-Hicks: I do not think it is desirable to make such a regulation. I have said that the police act with discretion. Quite conceivably it might happen that someone was ill in Bond-street and a medical practitioner might block the whole place for a couple of hours.

Proposed Removal of King's College.

Major Sir Richard Barnett asked the President of the Board of Education whether the recommendation of the Haldane Commission on the University of London to transfer King's College from the Strand to the Bloomsbury site behind the British Museum was likely to be carried into effect.—Lord E. Percy replied: King's College Council have intimated their unwillingness to contemplate moving King's College to the Bloomsbury site on the terms suggested. The Treasury are still in correspondence with the University of London on the subject.

Maternity Centres and Birth Control.

Mr. Thurtle asked the Minister of Health if he would make arrangements to give Parliament an opportunity of directing that maternity centres provided at the cost of public funds should be free to give information on birth control to such married women as desired it.—Mr. N. Chamberlain replied: Any question as to the possibility of arrangements being made for the discussion of this question on the floor of the House should be addressed to the Prime Minister.

Local Medical Research Committees.

Mr. Groves asked the Minister of Health whether he was aware that within the county borough of West Ham a medical research committee had been formed composed of all the medical staff of the borough council, certain of the staffs of the local hospitals, and several local medical practitioners, and that this committee had paid serious attention to the questions of cancer and tuberculosis; and whether, in view of the urgent necessity of this specially scientific research being national instead of local, he would consider the recommendation for the establishment of such local medical committees in all counties and through the Ministry of Health provide the highest specialists in these subjects to collaborate with all local medical workers in order that the greatest possible degree of efficiency be obtained.—Mr. N. Chamberlain replied: The answer to the first part of the question is in the affirmative. As regards the second part attention has already been called in memoranda issued from the department to the advantages which may be derived from the consideration of certain problems relating to cancer by local committees of this nature, and I do not doubt that they could do valuable work in other directions. It would be premature, however, at this stage to make any general recommendation to all counties or to set up the specialist organisation suggested.

The Danger from Mosquitoes and Flies.

Mr. Herbert Williams asked the Minister of Health whether his attention had been drawn to the fact that many parts of the country were now infested with mosquitoes and other flies, the bites of which often had very serious and occasionally fatal consequences; and whether his department was taking any steps to deal with the situation.—Mr. N. Chamberlain replied: The answer to both parts of the question is in the affirmative. This subject has received expert study in my department for some years, the results of which are put at the disposal of local authorities and individual inquirers, and are to be published shortly in collaboration with the entomologists of the British Museum (Natural History). I may add that it has been shown that the destruction of mosquitoes and the prevention of bites by these insects cannot be secured by the adoption of any single or simple formula. Any useful action must depend upon the identification of the species of mosquito prevalent in the area, and the adoption of measures appropriate to the natural history of that species.

Popular Education on Health Subjects.

Mr. Rennie Smith asked the Minister of Health whether he could take any steps to promote the medical education of the people.—Mr. N. Chamberlain replied: If, as I assume, the hon. Member's question refers to the provision of simple information of health questions, I may say that many local authorities already provide such information, and that my department have recently published a memorandum on public education in health by the chief medical officer which deals generally with such provision. A proposal to extend the powers of local authorities in this matter is now before Parliament.

Monday, June 22nd.

Consumption of Opium in India.

Mr. Morgan Jones asked the Under-Secretary of State for India whether he could give figures showing the consumption of opium in Calcutta, Rangoon, Amritsar, Bombay, Karachi, and Madras per 10,000 of the population; and whether he could state the normal amount per 10,000 considered adequate by the medical authorities in India.—Earl Winterton replied: The amounts consumed in Calcutta (including the suburbs and the towns of Howrah and Bally) and at Rangoon in 1923–24 were respectively 185 lb. and 226 lb. per 10,000. Figures for the other four towns mentioned are not available, but the amounts consumed in the districts of Amritsar, Bombay, Karachi, and Madras were respectively 56, 86, 43, and 53 lb. per 10,000. No pronouncement by the medical profession in India of the normal amount per 10,000 considered adequate is on record.

Colonial Medical Services.

Lieut.-Colonel Angus McDonnell asked the Secretary of State for the Colonies the percentage of local tax revenue expended on medical and sanitary services by the Governments of Kenya, Uganda, Tanganyika, Nigeria, Gold Coast, and Sierra Leone.—Mr. Amery replied: Taking the figures from the current estimates and including expenditure on sanitary services which is shown under other heads of the estimates, the percentages are Kenya 12·3, Uganda 20·8, Tanganyika 17·23, Nigeria 21·9, Gold Coast 16·3, Sierra Leone 16·7. The Nigerian figures are, however, abnormal owing to certain exceptional expenditure of a non-recurrent character.

Investigation of Sleeping Sickness.

Sir Geoffrey Butler asked the Secretary of State for the Colonies whether the Government of Uganda had been approached by the League of Nations with a request for the provision of hospitality at the Entebbe laboratory for a commission to investigate sleeping sickness; and what, if any, had been the reply returned.—Mr. Amery replied: The appointment of such a commission was recommended to the Council of the League by the International Conference on Sleeping Sickness which recently sat in London. No actual proposal has yet been received from the League, but I have ascertained that if such a proposal is made the Government of Uganda will gladly coöperate by placing the laboratory at the disposal of the commission.

Shortage in R.A.M.C. Officers.

Lieut.-Colonel Heneage asked the Secretary of State for War what was the shortage in Royal Army Medical Corps officers in the army; how many civilian doctors were employed instead; and what was the extra cost, if any, to the Exchequer.—Captain King (Financial Secretary to the War Office) replied: The shortage of Royal Army Medical Corps officers is 86. Of these, 30 would be under instruction at the Royal Army Medical College and elsewhere, leaving a shortage of 56 officers doing duty which is made up by employing 21 non-regular officers and 35 civilian practitioners. No extra cost to the Exchequer is involved.

Tuesday, June 23rd.

Maternity Centres and Birth Control Advice.

Mr. Thurtle asked the Prime Minister if, in view of the national importance of the matter, he could see his way to give the House an opportunity of directing that maternity centres provided at the cost of public funds should be free to give information on birth control to such married women as might desire it.—Mr. Baldwin replied: In the present state of public business it will be impossible to find time for this, unless an opportunity should arise on the estimates of the Ministry of Health

Cost of Investigating Excessive Prescribing.

Mr. Groves asked the Minister of Health if he was aware that his officers connected with the National Health Insurance had recently decided to charge against the funds of local insurance committees the cost of investigating excessive prescribing, and that these investigations were carried out for the purposes of his department; whether he would arrange for the necessary expenses incurred to be borne by his department and not imposed upon the local insurance committees; and whether he would state the names of the local insurance committees who had represented to this effect.—Sir Kingsley Wood replied: The hon. Member is under a misapprehension in suggesting that there has been any change of policy in this matter. It was always intended that the cost of the investigations to which he refers should be met from the funds available for the administration expenses of insurance committees. My right hon. friend is advised that the preparation of the statistical returns in question is properly a duty of these committees and he sees no justification for transferring the charge to the Exchequer. Representations in the sense indicated in the question were received from the insurance committees for Berkshire, Middlesex, the West Riding of Yorkshire, Birkenhead, Brighton, Liverpool, Reading, and Wigan.

Provision of Local Pathological Laboratories.

Mr. Groves asked the Minister of Health whether he had considered the handicap to local medical research committees in the non-provision of pathological laboratories in connexion with local hospitals; and whether, in connexion with the Government's plans of research work, he would consider the provision of such equipment for the use of local medical men.—Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) replied: There are no funds available at present for the provision of pathological laboratories for the assistance of local committees of this kind. In any future developments of health policy the provision of such laboratories will be borne in mind.

Hospitals for Expectant Mothers.

Colonel Day asked the Minister of Health whether, in view of the heavy death-rate among women during childbirth, due to conditions over which they had no control, he would take such action that would result in local authorities providing a greater measure of hospital accommodation for expectant mothers; and, in cases of necessity, would he consider making provision for payment of cash grants to the mother or to such associations as already provided assistance to mothers both during and after childbirth.—Mr. N. Chamberlain replied: As regards the first part of the question I would refer the hon. and gallant Member to the answer which I gave on May 20th on this subject. As regards the second part I would point out that grants are already made from the Exchequer to local authorities and nursing associations, which provide skilled assistance during childbirth, and that every woman who is the wife of a man insured under the National Health Insurance Act is entitled to receive a sum of £2 as maternity benefit on her confinement, and if she is herself insured, a further sum of £2 The whole question of the provision to be made for maternity in the case of insured women and the wives of insured men will doubtless receive the consideration of the Royal Commission on National Health Insurance, which is now sitting

Consumptives in London Prisons.

Colonel Day asked the Home Secretary if he was aware that there were insufficient cells set apart for prisoners suffering from tuberculosis in Pentonville and Brixton prisons, and, in consequence, such prisoners were sometimes put in the ordinary cells; would he take immediate action to improve the accommodation of sufferers from this disease in prisons; and, would he state if all ordinary cells so used were thoroughly disinfected after tuberculous patients had left them.—Sir W. Joynson-Hicks replied: The special cells for tuberculous cases, four at Brixton and eight at Pentonville, are sufficient for the usual average numbers of such cases Ordinary cells are not now used for tuberculous patients. When the number of cases exceeds the number of special cells, the patients are taken into the prison hospital and the rooms so used are disinfected afterwards.

Donations and Bequests.—The late Miss Pringle Home Douglas, of Edinburgh, left by will, among other bequests, £1000 to the Edinburgh Royal Infirmary, for general purposes other than building, and £500 to the Convalescent Home, Murrayfield, in connexion with the Edinburgh Royal Infirmary.—Mr. William Shillito, of Wootton, Eccleshall, Staffs., left the residue of his property, amounting to about £5000, to the Stafford General Infirmary, where he had formerly been a patient.—Mr. Henry Hayward, of Kennington, S.E., and Eastbourne, left £1000 to the Royal Hospital for Incurables, Putney, and £500 each to Dr. Barnardo's Homes, Fegans' Homes, Spurgeon's Orphanage, Children's Convalescent Homes, and Muller's Home, Bristol.—Sir Edward Elias Sassoon left £5000 to his executors for such charitable objects as they may think fit.—Mr. James Baugardt Elmslie, of Hyde Park, W., left £1000 to St. Mary's Hospital, Paddington.—Mrs. Louisa Sophia Nourse, of Surbiton and Brighton, left £2000 to the Seamen's Hospital Society (Dreadnought), Greenwich, S.E., to endow two beds for the treatment of seamen in memory of her late husband, £1000 each to the Metropolitan Convalescent Institution, Victoria-street, S.W., the Samaritan Free Hospital for Women, Marylebone-road, and the Hospital for Epilepsy and Paralysis, Maida Vale.—Mr. John Ratcliffe, J.P., of Micklehurst, Cheshire, left £2000 to Oldham Infirmary.—Colonel Thomas Johnson Seppings, of The Grange, King's Lynn, left £2000 to the West Norfolk and Lynn Hospital, of which £600 are for a Seppings bed in the men's ward.

PROPOSED MEDICO-LEGAL INSTITUTE FOR LONDON.

The annual meeting of the Medico-Legal Society was held in the Barnes Hall of the Royal Society of Medicine on June 23rd, under the presidency of Lord Justice Atkin, when a discussion took place on the suggestions made by a committee of the Council with the object of establishing in the metropolis a medico-legal institute.

The President said that no more important meeting had ever been held by the Society, nor could a proposal of greater seriousness be put forward in connexion with the matters with which the Society concerned itself. It was almost incredible to see how little provision was made in this great city for medico-legal research and teaching of any serious nature, in which lack London probably stood alone among the great centres of the world. Here there was no central institute, laboratory or museum, nor any organisation for giving unified teaching on such subjects. In saying this he fully realised that the medical schools were doing all they could in the matter according to the resources at their command. No one who had had anything to do with the administration of justice in this country could fail to appreciate the extraordinary importance of the proper development of medico-legal learning in reference to securing that justice was done; no session of any criminal court was ever held where topics of the greatest medico-legal importance were not introduced, and hence where it was not of the utmost importance that highly informed expert advice should be placed before the court. Though the country had been fortunate enough from time to time to be in possession of two or three really eminent experts upon whom reliance could be placed, it was still unfortunate that there had been no institute which would secure the general education of a sufficient number of people in the very highest branches of medico-legal work From the point of view of justice, when an expert was good he was very good, but when he was bad he was horrid. The need for this organised special training was even greater for defence than for prosecution, so as to arrive at the real truth.

Obviously in these days research must be unceasing; the modern criminal was making himself acquainted with all the latest developments of science, and it was essential that the State should be at least equally well armed.

Another matter of paramount importance was that instruction in medico-legal subjects was now part of the regular vocational instruction of those seeking a medical qualification; but clearly that instruction given at a number of different schools, none of which was specially equipped for the purpose, must be quite different from what that instruction would be if it could come from a central institute under the guidance and inspiration of some authority. He considered that proper instruction in medico-legal matters was as important for those who would practise the law—especially those in the criminal courts—as for those proposing to adopt the medical profession.

It was obviously impossible that such a far-reaching scheme as this could be carried out to any considerable extent by a society which was simply a scientific society. Very large interests were concerned. The Ministry of Health and the Home Office would be closely concerned with it; also public municipal bodies, and particularly the county council on account of its interests in the coroners. Similarly the great teaching bodies and London University were concerned. It would be impossible for such a project to proceed without the coöperation and benevolent interest of those various bodies.

The Need for Research.

Sir Bernard Spilsbury pointed out that the nine proposals set out in the circular were merely suggestions. He had received a communication from Sir Archibald Bodkin, who considered that the proposal to establish such an institute was of great public importance. The present arrangements for skilled pathological examination were far from perfect, and the records of cases of importance and of researches carried out in connexion with them were nowhere collected or registered so as to be available for study. The staff of such an institute could be consulted confidentially in any suspicious case by medical men and by coroners, or by the police, or by Sir Archibald himself. Sir Bernard Spilsbury said he had heard also from Sir George Newman, of the Ministry of Health, who said that the more he thought about the project the more he felt himself in favour of it, and he would gladly do all in his power to support the scheme. The speaker said this scheme had been in men's minds for a long time, and when Sir William Collins was President of the Society he referred to it. At a later date, in 1907, Dr. Pernet dealt with the same subject and drew a contrast between the teaching of medical jurisprudence in Paris and in this country, to the distinct disadvantage of the latter. The contrast was greater at the present time because Paris now possessed a medico-legal institute as part of the equipment for teaching the subject. Organised teaching in medical jurisprudence had been given at Edinburgh from the commencement of the nineteenth century. In London those who collected specimens, &c., reserved them for teaching in their own schools, and the number of such specimens had always been inadequate. Yet London presented an immense field of material. In a few years great headway could be made and systematic post-graduate teaching on the subject could be given; and it would become very important for any applicant for the post of police surgeon to have had the benefit of such a course.

There was great need for research into medico-legal problems such as post-mortem changes, and the teaching of chemistry and bacteriology was at present in a very unsatisfactory condition. With such a proposed institute available, bodies on which inquiries were to be made could be preserved in cold storage, to prevent post-mortem changes taking place in the meantime, before the judicial trial was held.

Teaching Facilities.

Sir William Willcox said some such idea as that under discussion had been in the minds of those engaged in teaching forensic medicine ever since the foundation of this Society. One of the greatest difficulties in the way of the establishment of such an institute was the financial one, and that had been the difficulty in carrying out medico-legal work in London; there had been no special grant by the Government for the carrying out of medico-legal work. Careful consideration of the many interests involved would be necessary in carrying this project forward. At present medico-legal teaching in London was much decentralised; ten medical schools were teaching forensic medicine, which meant a wasteful repetition of the same course. One of the great advantages of such an institute would be to enable police surgeons to have training, as they were usually the first to see the body in cases of alleged suicide or murder. Even when such an institute was established, the delicate and careful investigations necessary when a life was at stake could not be carried out in the presence of a class of students. The institute would also be of the greatest value to the coroners of the metropolis.

Sir William Collins said this Society had been very successful in a number of directions, but not in the matter of educational, legislative, or administrative reform in regard to medical jurisprudence. In 1907 the Society joined with the L.C.C. in a deputation to the Lord Chancellor of the time on the subject of a reform in the matter of death certification and Coroners' law. Twenty reforms were then suggested, but scarcely any of them had yet been achieved. In forensic medicine there was certainly much opportunity for improvement; indeed, there was a time in recent years when the teaching and examinations on the subject were better than now. He had himself advocated the teaching of medical jurisprudence in London at fewer centres. But in the matter of administration it was possible to over-concentrate, and, except for greatly concentrated study of detail in a given case, he would not favour the centralisation of the work of making post-mortem examinations. Neither did he favour the idea that the control of investigation and research should be largely in the hands of a Government department, as it might tend to beaurocracy and stereotyping.

How to Carry the Proposals into Effect.

Dr. Halliday Sutherland asked as to the proposed steps to be taken to carry the proposals into effect if this meeting approved of the principle.

The President replied at once that if the meeting approved the principle of the proposals, the Committee would be authorised to take such steps as they thought necessary to develop the proposals and coöperate with all the interested parties, with power to add to their number. At a later stage, no doubt, they would report to the Society. He hoped that at a future date there would be a very large meeting, not confined to this Society, when, indeed, the matter might have so grown that the Society was no longer taking the lead. It would be a great step if, as a commencement, some laboratory accommodation and the nucleus of a museum could be secured.

Mr. Costello thought the project should remain in the hands of this Society and not be under the control of a Government department. He once asked for information as to prosecutions of butchers for exposing for sale tuberculous meat, and after many weeks of delay and receiving an acknowledgment from three departments to which his letter had been successively sent, he had no information whatever supplied. The usual post-mortem examinations made by medical practitioners were inefficiently done, and most of the legal disputes concerning deaths were due to the fact that an expert post-mortem examination had not been made.

Dr. M. I. Finucane thought the matter so important that it should be a Home Office question, and not one to be set going by a private society.

Sir Walter Fletcher contended there was an urgent national need for such an institute; it became largely a question of ways and means, and he feared the statutory difficulties would prove to be the more serious. From the standpoint of scientific research the proposal was of the greatest importance, and this work really placed under contribution all the sciences. He hoped future activities would succeed in linking the proposed organisation very firmly with existing laboratories and scientific research centres.

Mr. Ingleby Oddie, speaking as a coroner, referred to the great waste of valuable instructional material in London. There were available in London not more than half-a-dozen expert men, and as no organised training of experts was in progress, he asked what was to be done if anything happened to the few men in question.

Dr. A. S. Woodwark said he would like to see more attention paid to the matter of instruction in these matters in those whose function would be on the legal side. Half the battles fought in the law courts were directly due to ignorance on both sides. Also a very important sphere of work for the institute would be that connected with industrial diseases, matters of compensation and the like.

Dr. A. Hayden suggested that the matter was of sufficient importance to justify asking for a Royal Commission. This would not only bring it before the public, but might bring in subscriptions.

Dr. Godfrey Carter (Sheffield) hoped something tangible would eventuate from the proposal, as certainly the provinces needed a stimulus in the matter of teaching medical jurisprudence.

A Resolution Carried.

The President briefly summed up and replied to some of the points raised in the discussion. A Royal Commission, though sometimes bringing desirable results, had, on occasion, proved a means of shelving a subject. He did not think the Home Office or any other department would seek to manage such a concern. He agreed that industrial diseases and questions might well come within the range of the institute's activities. There was still much requiring to be done in association with the kind of problems which were continually being brought into the courts. There could be no idea of at once starting in a splendid building, full equipped, but it was essential that some sort of start should be made, and then, he did not doubt, the matter would develop. His lordship proposed, from the chair: "That this meeting expresses its general approval of the proposal for establishing a medico-legal institute, and requests the Committee to take such steps as they may think necessary to develop the proposal, in coöperation with all interested parties, with power to add to their number." This was unanimously carried.

The President said the Committee would report to the Society from time to time when any definite results could be communicated.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Wednesday, July 1st.

ANNUAL GENERAL MEETING OF FELLOWS: at 5 P.M. To receive the annual report of the Council.
Election of Officers and Council for Session 1925–26.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, June 29th, to Saturday, July 4th.—West Lecture Hall, Royal Society of Medicine, 1, Wimpole-street, W. Lecture arranged by the Fellowship of Medicine and open to all members of the medical profession. At 5.30 P.M. on Friday, July 3rd, Sir John Thomson-Walker on Urinary Infections.—London Temperance Hospital, Hampstead-road, N.W. Special Post-graduate Course for practitioners. Second week. Daily, 4.30 to 6 P.M. Clinical demonstration for one hour on medical and surgical cases, the ultra-violet lamp, Some Syphilitic Skin Lesions. Lecture for half an hour.—St. Peter's Hospital, Henrietta-street, W.C. Post-graduate Course in Urology. Clinical work every afternoon in the Hospital. Lectures: Monday, Mr. J. Alban Andrews on Genito-Urinary Tuberculosis; Tuesday, Mr. J. Swift Joly on Urinary Calculi; Wednesday, Mr. Clifford Morson on Urinary Antiseptics; Thursday, Mr. F. J. F. Barrington on Non-Tuberculous Infections of the Urinary Tract; and Friday, Sir John Thomson-Walker on Urinary Obstruction.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, June 29th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Mr. Bishop Harman: Eye Dept.

Tuesday.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Addison: Operations.

Wednesday.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Mr. Tyrrell Gray: Operations.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 12 noon, Surgical Registrar: Surgical Pathology 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—11 A.M., Dr. McDougal: Electrical Dept. 10.30 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

Thursday, July 2nd.—5 P.M., Mr. L. G. Phillips: Intracranial Hæmorrhage.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, June 30th.—4.30 P.M., Dr. F. Thomson: Cases illustrating the Early Diagnosis of the Infectious Fevers (at the North-Eastern Hospital, St. Anne's-road, N.).

Friday.—4.30 P.M., Mr. Aubrey Goodwin: Expectant Obstetrics.

Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, June 30th.—5 P.M., Dr. Roxburgh: Diseases of Nails.

Thursday, July 2nd.—5 P.M., Dr. Haldin Davis: Peculiar Forms of Psoriasis.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, July 2nd.—4 P.M., Dr. Nabarro: The Cerebrospinal Fluid in Health and Disease.

Appointments.

Hoskins, W. D., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the St. Just District of the County of Cornwall.

Ingram, John T., M.B., B.S.Lond., M.R.C.S., Physician to Out-patients to the Evelina Hospital for Sick Children, Southwark.

Symons, A. D., M.D. Bristol, M.R.C.S., D.P.H., Medical Officer of Health, School Medical Officer, &c., for Shrewsbury.

University of Leeds: **Dobson, J. F.**, M.S. Lond., F.R.C.S. Eng., **Collinson, H.**, M.S. Lond., F.R.C.S. Eng., Professors of Clinical Surgery; **Braithwaite, L. R.**, M.B., Ch.B. Manch., F.R.C.S. Eng., Director of Surgical Research.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Second Asst. in Pathology. £250 12*s.*
Birmingham, City Mental Hospital.—Asst. M.O. £350.
Birmingham and Midland Hospital for Skin, &c.—Hon. S.
Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Res. M.O. £250.
Bolingbroke Hospital, Wandsworth Common, S.W..—Hon. Asst. S. to Ear, Nose, and Throat Dept.
Bolton, Townleys Hospital, Farnworth.—Second Asst. M.O. £225.
Bradford Royal Infirmary.—Res. Surg. O. £250.
Bury County Borough.—Asst. M.O.H., &c. £600.
Cambridge, Addenbrooke's Hospital.—H.S. at rate of £130.
Chester Royal Infirmary.—Hon. Asst. S.
City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. at rate of £100.
Colindale Hospital, Hendon, N.W.—Jun. Asst. M.O. £500.
Croydon County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.
Croydon General Hospital.—Cas. H.S. £100.
Dover Borough.—Asst. M.O.H. £750.
Dudley Guest Hospital and Eye Infirmary.—H.S. £175. Also Asst. H.S. £150.
Dumfries and Galloway Royal Infirmary.—Jun. Res. M.O. £125.
Dundee, University College.—Chair of Anatomy.
Edinburgh, Chalmer's Hospital.—Res. M.O. and Res. S.O.
Epsom, The Manor.—Jun. Asst. M.O. £440.
Halifax Royal Infirmary.—Hon. Radiologist.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. for six months. £50.
Hull, Institution Infirmary, Beverley-road.—Res. Asst. M.O. £350.
Ilford Urban District Council.—Asst. M.O.H. £600.
Liverpool, Mill-road Infirmary.—Res. Asst. M.O. £200.
Liverpool, St. Paul's Eye Hospital.—Two Hon. S.'s.
London Hospital Dental School, E.—Asst. Dental Anæsthetists. £25 each.
London Hospital, E.—Two Hon. Asst. Aural S.'s. Also First Asst. to one of the five Surg. Firms. £400.
London Lock Hospital, 283, Harrow-road, W.—Second H.S. £150.
London School of Hygiene and Tropical Medicine.—Lecturer on Trop. Hygiene. 200 guineas per annum.
Manchester, Crossley Maternity Hospital, Ancoats.—Half-time Res. M.O. at rate of £50.
Manchester Royal Infirmary and Dispensary.—Hon. Asst. Gynæcol. S.
Manor House Hospital, Golders Green, N.W.—H.S. £200.
National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P.
New Zealand Government, Mental Hospitals Dept.—Two Asst. M.O.'s. £615.
Notts Education Committee.—School Dentist. £500.
Porth and District Hospital, Glam.—Res. S. £750.
Royal Westminster Ophthalmic Hospital, King William-street, Strand, W.C.—Refraction Asst. at rate of £100.
Sheffield, Jessop Hospital for Women.—Sen. Res. O. at rate of £250.
Sheffield University and Jessop Hospital for Women.—Asst. Path. and Demonstrator of Anatomy. £300.
Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.
Sunderland Royal Infirmary and Children's Hospital.—Hon. S. for Nose, Throat, and Ear work.
Surrey County Council.—Asst. M.O.'s in Pub. Health Dept. £600.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Each at rate of £100.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. S.

West Ham Union.—Dist. M.O. £914.

Westmorland County Education Committee and Kendal Borough Education Committee.—Dental Practitioner. £500.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Pickering, Yorks, N. Riding; Barnstaple, Devon; Broughton-in-Furness, Lancs; Durham, Durham; Helsby, Cheshire; Loanhead, Edinburghshire; and Chulmleigh, Devon.

Births, Marriages, and Deaths.

BIRTHS.

BLAKE.—On June 14th, at Oakley House, Acle, the wife of Eliot Blake, M.R.C.S., of a daughter.

FORREST.—On June 19th, at 10, Coates-crescent, Edinburgh, the wife of A. W. Forrest, M.A., M.D., D.P.H., Wandsworth Common, S.W. 18, of a son.

FORSTER.—On June 16th, at Upper Duke-street, Liverpool, the wife of Henry Vincent Forster, M.C., M.B., Ch.B., of a son.

HOOPER.—On June 14th, at a nursing home, Caversham, the wife of Norman Hooper, of a daughter.

LAPAGE.—On June 17th, at Barton House, Didsbury Park, Manchester, to Dr. and Mrs. C. P. Lapage, a daughter.

MILNE.—On June 12th, at 18, Walker-street, Edinburgh, to Dr. and Mrs. C. G. S. Milne, MacRobert Hospital, Cawnpore, India, a son.

MARRIAGES.

ALDRED-BROWN—CROWE.—On June 17th, at Holy Trinity Church, Brompton, Ronald Aldred-Brown, B.M., B.Ch. Oxf. to Doreen Mary Barby Crowe, only daughter of Colonel and Mrs. P. B. Crowe, of Gilston-road, South Kensington.

HOLDEN—DRYSDALE.—On June 6th. at St. Mary's Church, Guildford, Dr. S. J. C. Holden, County Medical Officer of Health, Buckinghamshire, son of the late Rev. Joseph Holden, Vicar of Antrotus, Cheshire, to Jean, elder daughter of Mrs. Drysdale, King's Corner, Guildford.

STIRLING—MATTHEW.—On June 20th, at St. Columbia's, Pont-street, Major A. Dickson Stirling, D.S.O., R.A.M.C. to Isobel, only surviving daughter of the Rev. and Mrs. L. C. Matthew, Warwick-avenue, Bedford.

TAIT—ALFORD.—On June 20th, at St. Matthias's, Richmond Hill, Greville Brend Tait, M.B., B.Ch., to Elizabeth Joan, elder daughter of Mr. J. S. Alford and Mrs. Alford, of Richmond, Surrey.

THOMSON—MCLEAN.—On June 20th, at the Presbyterian Church, Highgate, Douglas McKenzie Thomson, M.B., C.B., Arbroath, to Mary Elizabeth McLean, niece of Captain and Mrs. Warden, Talbot-road, Highgate, London.

DEATHS.

COKE.—On June 19th, at Fitzgeorge-avenue, West Kensington. Edmund Percival Isaacs Coke, M.R.C.S., L.R.C.P., aged 56,

NIGHTINGALE.—On June 20th, at Busketts, Woodlands, near Southampton, after a short illness, Samuel Shore Nightingale, M.R.C.S., L.R.C.P., D.P.H., in his 65th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTTINGHAM GENERAL HOSPITAL: THE RANSOM MEMORIAL.—As a tribute to the memory of Dr. William Henry Ransom and his son, Dr. William Bramwell Ransom, of Nottingham, a new pathological department was opened at the Nottingham Hospital recently by Sir John Rose Bradford. Sir Charles Seeley presided, and among those present were the Bishop of Southwell, Mr. F. Acton, Dr. F. H. Jacob and Mr. J. K. Wright. Dr. W. H. Ransom was honorary physician to the hospital from 1854 to 1890, when on his resignation his son carried on the duties till 1909. Sir John Rose Bradford said that the two men whose names the hospital extension would perpetuate did not confine themselves to the narrow pursuit of their profession, but took an active part in the promotion of all work designed to make the individual more efficent for the discharge of his duties as a citizen. The period covered by father and son had seen a great advance in medicine, and both had borne their full share of the work upon which progress had been based. Sir John Rose Bradford referred to the fact that during the first half of the life of the father fever was detected by the hand of the physician, while at the time of the birth of the son the thermometer was being used for that purpose. The value of laboratories and laboratory methods in the daily work of medicine, said Sir John Rose Bradford, was now so universally recognised that not only could no hospital dispense with them but no practitioner could do his work without having means of access to a laboratory. As the Ransoms had been remarkable as pioneers in recognising and in developing laboratory methods, the form which the memorial to their memory had taken was singularly appropriate.

Notes, Comments, and Abstracts.

LARVICIDES IN MOSQUITO CONTROL.*

By JOHN F. MARSHALL,
DIRECTOR OF THE MOSQUITO CONTROL LABORATORY, HAYLING ISLAND, HANTS.

IN Great Britain 25 different species of mosquitoes are at present known, only three of these belonging to the Anopheline tribe. The British mosquitoes may be roughly divided into three general classes—namely, (1) domestic mosquitoes, which breed largely in collections of water near dwelling houses; (2) rural mosquitoes, which breed in the stagnant and non-salt water of ditches, pools, or swamps; and (3) salt-water mosquitoes, which breed in stagnant salt, or partly salt, water. Along the south coast there are probably only five species of mosquitoes which require consideration from the "nuisance-producing" point of view. These are (1) the Anopheline mosquito, *Anopheles maculipennis*; (2) and (3) the "domestic" mosquitoes, *Culex pipiens* and *Theobaldia annulata*; (4) the "rural" mosquito, *Ochlerotatus rusticus*; and (5) the "salt water" mosquito, *Ochlerotatus detritus*. With the exception of (1), all these mosquitoes belong to the Culicine tribe. Mosquitoes belonging to the Culicine tribe are incapable of transmitting malaria, but they must not, on this account, be regarded as harmless insects, since their bites may be followed by serious, and even fatal, results. There are many localities in England (some of them even in the near neighbourhood of London) where mosquitoes create an almost intolerable nuisance throughout every summer and autumn.

Methods of Attack.

Experience has shown that the only effective means of controlling mosquitoes is to attack them in the larval stage, either by destroying the larvæ or by abolishing the stagnant water which is essential for larval existence. In the first case, the larvæ are either (1) suffocated by covering the surface with a film of paraffin, or (2) poisoned by mixing larvicides with the infested water. In the second case, various engineering methods are made use of to prevent the stagnation of water.

[Mr. Marshall then discussed these various methods, all of which are now well established in the fight against mosquitoes. With regard to larvicides, he said:—]

For a larvicide to be of any practical use in mosquito control work, it must be (1) inexpensive, (2) harmless to human beings or animals who may happen to drink the water treated, and (3) effective in action whether the water to be treated is fresh, brackish, or salt. Experiments carried out at Hayling over three years ago with regard to the larvicidal qualities of various substances showed that a specially prepared sanitary fluid containing 20 per cent. of soluble cresol and known as White Cross disinfectant gave extremely satisfactory results both in the laboratory and in the field. In a dilution of 1 part in 16,000 it killed the larvæ of *Ochlerotatus detritus* in one hour; in a dilution of 1 in 32,000 in one and a half hours; and in a dilution of 1 in 48,000 in three and a half hours. This fluid gave perfectly satisfactory results when the larva-infested water was partly, or even wholly salt. The only point that requires attention when this fluid is being used with brackish or salt water is the fact that it should be mixed with a little fresh water before being used; it will then diffuse readily in the water to be treated, however high the proportion of salt water present.

Calculating the Amount Required.

If a breeding-place has a surface area of A square yards and an average depth of *d* inches, the number of gallons of larvicide that must be put in to attain any desired "strength" of 1 part in "*n*" parts is given by the formula—

$$\frac{14 \times A \times d}{3 \times n}$$

If the larvicide is used in a proportion of 1 part in 28,000, which is a suitable "strength" in the case of White Cross fluid, the above formula reduces very simply to—

$$\frac{A \times d}{6000} \text{ gallons.}$$

That is to say, to calculate the number of gallons of the above larvicide required to treat any given piece of water, it is only necessary to multiply the surface area in square yards (A) by the average depth in inches (*d*) and divide the product by 6000. Say, for instance, that the piece of water to be treated is 100 yards in length, 15 yards in width, and 6 inches in (average) depth, then the area A is 1500 square yards, and the amount of larvicide required is

---

* Abstracted from a paper on the Control of Mosquitoes read before the Portsmouth Literary and Philosophical Society.

$$\frac{1500 \times 6}{6000} \text{ or } 1\tfrac{1}{2} \text{ gallons.}$$

When adding the larvicide to the infested water, care should be taken to distribute it as uniformly as possible. In any case it is better first to dilute the total "dose" with three or four times its bulk of fresh water and then introduce the mixture by instalments. One way is to use a watering-can with a rose nozzle, the operator wearing "waders" and treating successive "strips" of the water. Another very effective method is to "sling" the successive instalments of the mixture out of an ordinary handbowl. Very little practice is required to distribute the mixture uniformly and rapidly in this way.

Safety of Domestic Animals.

A great deal of prejudice exists against the use of larvicides, owing to the popular idea that anything which is capable of killing a mosquito larva will render the water equally unsafe for domestic animals, or even human beings, who may happen to drink it. To show the fallacy of an argument of this kind, consider the case of White Cross disinfectant, and assume that it is being employed in a strength of 1 in 28,000, which is the proportion recommended. Water thus treated may be drunk by domestic animals with absolute impunity. The constituents of this fluid are, indeed, actually employed in veterinary medicine —and even to obtain a *safe medicinal dose* of the very diluted mixture in question a cow would have to drink more than 100 gallons, a horse more than 80 gallons, a pig more than 20 gallons, and a dog more than 10 gallons. Even a hen would not have taken her safe medicinal dose until she had consumed just on 2 gallons of the treated water. There is, therefore, no danger whatever to be apprehended from the use of this liquid in the proportion necessary; and in the treatment of open and exposed breeding-places its use is much to be preferred to that of paraffin.

In dealing with sheltered breeding-places, the question of which method shall be adopted is largely one of expense. It must be remembered that when paraffin is used the amount required depends only upon the area of surface to be treated; but in the case of a larvicide, which has to diffuse throughout the whole body of water, the depth of the water is also an important factor. If the thickness of an effective paraffin film is assumed to be 1/1500 inch, then the cost of treating a piece of water of depth d inches with a larvicide which is c times as expensive as paraffin, and which has to be mixed with the infested water in a strength of 1 in n, is

$$\frac{1500 \times c \times d}{n}$$

times the cost of paraffining the same piece of water. In the case of any larvicide for which c and n are known, it is easy to calculate the depth of water at which the cost of paraffining and larviciding are the same. With White Cross fluid, for example, the dilution recommended is 28,000 and the cost about four times that of paraffin. Insertion of these values in the above formula shows that the depth in question is 4⅔ inches; and for any depth less than this the larvicide in question is the more economical method of the two.

Nuisance at Seaside Resorts.

In intertidal areas where sea water is allowed to accumulate and stagnate, the larvæ of the salt-water mosquito (*Ochlerotatus detritus*) are generally to be found in enormous numbers throughout every month of the year. The adults of this species (which hatch out almost continuously from April until November) have a much greater range of flight than any of the non-salt water mosquitoes; and this fact considerably increases the difficulties of mosquito control work in low-lying coastal districts. It may be stated definitely that the "mosquito nuisance" experienced in so many of our seaside resorts is most frequently caused by salt-water mosquitoes invading the residential district from breeding-places situated on the outskirts of the town. Hence the attempts occasionally made by local authorities to alleviate the nuisance by paraffining collections of stagnant water within the residential district only are in the majority of cases to be deprecated; not only because they are a sheer waste of public money, but also because their futility tends to diminish public confidence in anti-mosquito work generally.

As regards the various species of mosquitoes which breed in non-salt water, it should be noted that long-established collections of water, such as ornamental lakes, cattle ponds, &c., frequently contain fish, water bugs, and other creatures which devour mosquito eggs and larvæ and thus render mosquito breeding impossible. Under these conditions the addition of larvicide is not only unnecessary but may actually do harm by destroying some or all of the benevolent "mosquito enemies" present. Hence water should never be treated with larvicide unless the presence of larvæ has been actually observed.

NATIONAL COUNCIL FOR THE UNMARRIED MOTHER AND HER CHILD.

THE annual meeting took place at Carnegie House, 117, Piccadilly, on June 18th, under the presidency of Lord Henry Cavendish-Bentinck, his place being later taken by Mrs. H. A. L. Fisher. The annual report and balance-sheet were read and passed, and the officers and members of the executive committee were elected. Mrs. W. A. Potts, of Birmingham, read a paper on the Mental Deficiency Act as it affects Unmarried Mothers. A considerable number of the unmarried mothers who applied for Poor-law relief, she said, were mentally defective, and they constituted the real problem. The Mental Deficiency Act provided for placing in an institution or under guardianship women who were mentally deficient and were in receipt of Poor-law relief; the guardians therefore incurred responsibility if they discharged a mother of more than one illegitimate child without bringing the facts before the Mental Deficiency Committee. Among cases known to her personally who had been discharged without examination, Mrs. Potts mentioned: (1) A girl of 16 with two illegitimate children. She had a mentally defective brother aged 25. (2) A woman of 30 with four illegitimate children. There was a defective sister of 27. (3) A girl of 19 with two children. She had attended a special school. It was far the most merciful thing to put these women under supervision. They would only be properly cared for when the Mental Deficiency Act was used to its full extent.

Lady Nott-Bower said the question of certification was difficult because, before a doctor could certify a girl as mentally deficient, he had to produce evidence of deficiency from an early age. She advocated the establishment of more hostels under good management, where the girls could have work graded according to their capacity. The babies should remain with their mothers up to the age of 2 years, after which there were a good many associations which took children without their mothers. It was pointed out in discussion that the fact of sexual obsession implied in having several illegitimate children did not of itself constitute certifiable mental deficiency.

MOTHERCRAFT.

THE well-known little book entitled "Mothercraft,"[1] which consists of a selection from lectures delivered under the auspices of the National Association for the Prevention of Infant Mortality, has almost reached the stage when it might well be called the "Mothercraft Annual." Each edition, and this is the fifth, has shown signs of careful revision, and while the size of the book has not been greatly altered, the material it contains represents the very latest teaching on all the various branches of the "craft." Miss Norah March's article on the psychology of the infant in this edition is something rather novel, and while prevention is an admirable slogan when dealing with mental as well as with physical disorders, it is doubtful whether the average mother will effectively understand much of this article. An advertisement for ultra-violet light lamps has crept into the middle of an article on the sun-cure and its substitutes by Percy Hall, but despite these minor defects, the book still remains a most valuable guide to the subject of mothercraft, the essentials of which, as Dr. G. F. Still says in his introduction, "it is high time that every girl as a part of her education should be required to learn."

COLONIAL MEDICAL SERVICES: EXPENDITURE ON RESEARCH.

IN reply to questions by Lieut.-Colonel Angus McDonnell in the House of Commons on June 15th and 22nd, Mr. Amery gave some figures of expenditure on medical research work in certain Crown Colonies and Protectorates. Such expenditure, said Mr. Amery, is provided separately in the Budget of each Colony or Protectorate, and in view of the additions made to the territories the figures would not give a satisfactory standard of comparison. He contented himself, therefore, with giving, so far as they can now be ascertained, the amounts provided for the years 1901 and 1924 for Trinidad, Hong Kong, and the Gold Coast respectively, as representing three of the four important divisions of the Colonial Empire. The fourth, East Africa, was not administered by the Colonial Office in 1901. Expenditure on medical research was, he added, not distinguished from other medical expenditure, and it was still the case that a good deal of the research that was done was not, as a rule, separately provided for.

Ceylon.

1910–11.	1923–24.
No special provision was made in the estimates for medical research. Rs.4,407,329 were provided for medical (including sanitary services) of which Rs.753,666 represented the salaries of qualified medical officers.	Provision was made for an expenditure of Rs.70,142 on medical research—i.e., a special investigation into malaria—and of Rs.7,488,600 in respect of medical and sanitary services. Included in the latter sum was a total of Rs.1,489,125 for the salaries of qualified medical officers.

Medical research not separately shown.

Jamaica.

No figures are available as to the amount spent on medical research. The total expenditure on medical and sanitary services (including salaries) was: 1910–11, £64,685; 1923–24, £125,485. The salaries of qualified medical officers were: 1910–11, £11,815; 1923–24, £19,469.

GUERNSEY: VICTORIA COTTAGE HOSPITAL.

THE thirty-seventh annual report of this institution (for 1924) reveals a welcome, though unfortunately rare, state of financial prosperity. The total expenditure for the year 1924 was £1943 and the total income amounted to £3223. Of this sum £1232 counted as extraordinary income, being due to legacies and bequests, and was transferred to the capital account, leaving a credit balance of £48, surplus of income over expenditure. The hospital stands in a healthy situation in a suburb of St. Peter Port, overlooking the sea. It contains 25 beds, a well-equipped operating room, and an X ray department. Any medical man practising in Guernsey is eligible for election on the honorary medical staff, and is entitled to attend his own patients in the hospital. There is no out-patient department. Dr. P. S. Hichens, late honorary physician to the Northampton General Hospital, has just been appointed honorary secretary in succession to the Rev. J. D. Stevens, retired. During the year 1924 348 patients (189 males and 159 females) were admitted to the hospital—the greatest number yet admitted during one year. Of these, 133 were charged from 15*s.* to 20*s.* a week, according to their circumstances, the rest being treated free. The daily average of beds occupied was 15 and the cost per patient per day 7*s.* 7*d.* There were 16 deaths during the year—eight medical and eight surgical cases. 256 operations were performed (an increase of 38 on the previous year). Among the surgical cases there were as follows: Tonsils and adenoids operated on, 63; diseases peculiar to women, including two Cæsarean sections, three of ectopic gestation, and four of cancer of breast, 42; appendicitis, 38; hernia (two strangulated), 9; fractures, 13; dislocations, 5. There were no cases of rickets in this hospital, possibly owing to the abundant sunlight for which Guernsey is renowned. In addition to the Victoria Hospital there are three State hospitals in Guernsey—the Town Hospital in St. Peter Port with 195 beds, the Country Hospital in the centre of the island with 160 beds, and the King Edward Sanatorium, an isolation hospital for infectious diseases.

MERCUROCHROME IN GONORRHŒA.

To the Editor of THE LANCET.

SIR,—In your issue of June 20th Mr. W. H. Martindale recalls the serious misprint in Young's original article wherein 2·5 per cent. was made to read 25 per cent. It is also true, as he remarks, that the drug has been severely criticised; but this is not to say that it is wholly without value.

Mercurochrome-220, the disodium salt of dibromo-oxymercuri-fluorescein, links an antiseptic with a dye in the effort to attain a tissue-penetrating effect impossible with a colloid by reason of its physico-chemical nature. The writer was favoured with an early supply, but found it usually too irritating for use in urethritis, even a 1 per cent. aqueous solution causing intense and persistent pain in certain patients. In one instance the use of a 5 per cent. solution in the male urethra produced symptoms of renal congestion; and quite a number of cases of mercurial poisoning have been reported following its injection intravenously. It has numerous incompatibilities, including most anæsthetics, only those without basic properties—e.g., saligenin or benzyl alcohol—being permissible.

On the other hand, provided its staining properties be not objected to, a 2 or up to 5 per cent. solution is an excellent application for surface lesions, and equally useful for balano-posthitis or for painting the vaginal walls, from which absorption is slight. A colleague has reported in THE LANCET the routine use of a 25 per cent. solution for painting the vagina in children, but apart from obvious dangers it is questionable if any object is served by the employment of so strong a concentration.

I am, Sir, yours faithfully,
H. D. L. SPENCE.
Great Russell-street, London, W.C. 1, June 19th, 1925.

A USEFUL AND VALUABLE APPLIANCE.

To the Editor of THE LANCET.

SIR,—About a month ago, whilst opening and closing a drawer in my dining-room sideboard, the idea occurred to me that much benefit and comfort might be obtained by sick persons and chronic invalids by adapting a similar sliding arrangement to what is known as the "bed-pan." The provision necessary for carrying out what I suggest is: (1) A hole of sufficient size and suitable shape in the mattress and wire sheeting on which it lies; (2) a sliding shelf to which the bed-pan is affixed; (3) a frame standing on four legs like an ordinary chair, in which the shelf can be applied or withdrawn. At the end of each leg is a castor or small swivelled wheel, and this enables the nurse or attendant to push under or withdraw the shelf containing the bed-pan from the hole in the mattress and wire sheet. (4) A simple mechanical arrangement working with a handle and screw for placing in position *from below* the cover for the hole in the mattress and wire sheet and taking care that it fits accurately so that the patient does not experience any edge, ridges, or projections.

I am, Sir, yours faithfully,
Preston, June 21st, 1925. R. C. BROWN.

BALL'S MODERN OPHTHALMOLOGY

By JAMES MOORES BALL, M.D., LL.D., of St. Louis,

Member of the Ophthalmological Society of the United Kingdom; late Ophthalmic Surgeon to the St. Louis City Hospital; Author of *Andreas Vesalius the Reformer of Anatomy*, &c., &c.; Founder of the Ball Ophthalmic Museum, located in the Army Medical Museum, Washington, D.C.

The publishers believe that the new FIFTH Edition of this standard American treatise on Ophthalmology will meet with favour. The entire work has been rewritten; it will appear in new type; and is to be issued in TWO ROYAL OCTAVO VOLUMES, of about 720 pages each; containing nearly 500 Text-Illustrations and numerous Figures on Colored Plates.

THE F. A. DAVIS COMPANY, PHILADELPHIA (*PUBLISHERS*).

Farbwerke vorm. Meister Lucius & Brüning, Hoechst a. M., Germany.

The Organic Gold Preparation

TRIPHAL

(Sodium Aurothiobenzoimidoazol-carbonate)

for the specific treatment of

TUBERCULOSIS

More readily tolerated than the preparations of gold hitherto available and equally effective. Administered intravenously in doses of 0.025 gm. to 0.2 gm.

Original Packing:—Ampuls of 0.01 gm., 0.025 gm., 0.05 gm., and 0.1 gm.
Hospital Packing:—Each contains 10 Ampuls.

Literature will be sent to Medical Men at any time on request through:

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach**, for **Aiding** the **Digestion** and for **Sustaining** and **Strengthening**. **Valentine's Meat-Juice** is **Extensively Employed** in the treatment of

Phthisis.

Dr. Gouel, *Physician in Chief of the Villepinte Hospital for Consumption, Paris, France*: "VALENTINE'S MEAT-JUICE succeeds well in cases of Anæmia and in the treatment of Tuberculosis in an advanced stage when the stomach is intolerant."

Dr. Pietro Borromeo, *Physician and Surgeon of the Hospital of Rome, Italy*: "I have tried VALENTINE'S MEAT-JUICE in the Tuberculosis Division of the Hospital of the Holy Spirit, and have proved the great advantages that it renders for the nutrition of the consumptive. Pleasant to the taste of the most fastidious of the sick, it does not irritate the stomach; but stimulates the peptogastric functions so as to improve notably the appetite, even in cases of continuous and high fever and extreme loss of strength."

For sale by European and American Chemists and Druggists.

Stocked by all leading wholesalers.

The New Jaeger Underwear

A Consulting Physician writes:—

"In my opinion this invention of a Two-layer stockinet weave constitutes a distinct advance. The layers are so ingeniously woven that, for all practical purposes, the material behaves as a single fabric, whilst the air contained within the meshes acts as a bad conductor of heat, renders the garments more hygienic and, at the same time, lighter in weight than their somewhat bulky winter-weight predecessors.

In wear the fabric is warm and comfortable, and the texture is fine enough not to be irritating."

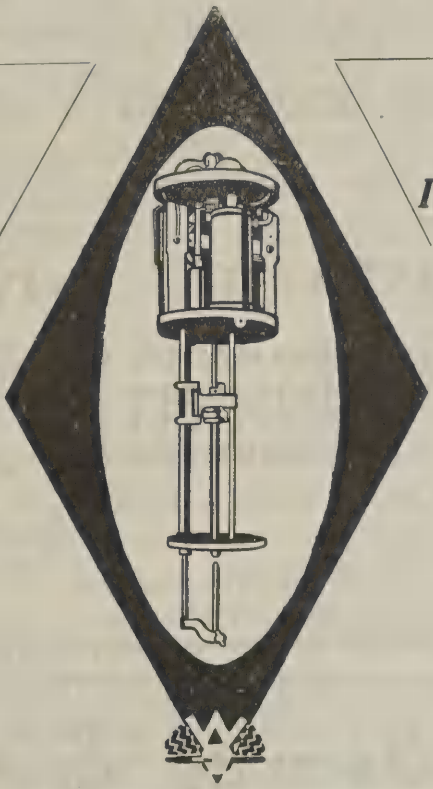
Artificial Sunlight Treatment

CARBON ARC LAMP



FOR GENERAL IRRADIATION

The above equipment is but one of the various types of apparatus described in our Bulletin No. 67, which gives a complete summary of the theory and practice of photo-therapy, or the treatment of disease by ultra-violet radiation. This apparatus is suitable for general irradiation and has many important advantages—intensity, automatic regulation, the capacity to work for long periods without renovation, extreme simplicity, etc. It is especially suitable for the general practitioner. Details of this equipment and of a variety of other apparatus suitable for every branch of photo-therapy are given in the pamphlet as well as a useful summary of the whole subject.

Practitioners contemplating the installation of apparatus suitable for the practice of photo-therapy will find the information contained in this booklet of the utmost value. It will help them to form a reliable estimate of the relative value of the various sources of radiation and to decide which type of equipment is most suitable for their own use.

A copy of the Bulletin will be sent gratis to all who will send a post-card to the address given below.

Deafness in Private Practice

Letters received by Mr. Dent from Medical Men in private practice suggest that the following information concerning the nature and scope of **"ARDENTE-ACOUSTIQUE"** may be welcomed where an opportunity for a thorough personal investigation has so far not arisen.

There is a wide range of distinct types of **"ARDENTE-ACOUSTIQUE,"** each separately designed for a specific condition of ear trouble and capable of further minute adjustment in each case. The selection of an appropriate type is based upon the personal information of the physician or indicated in his prescription.

Individual adjustment is subsequently made as a practical test suggests. For this purpose it is eminently desirable that a personal visit from the patient is arranged. Many physicians prefer to be present during these tests and their presence is at once welcome and obviously helpful.

Fitted with an exclusive **NON-HEAD ATTACHMENT** it is practically invisible. Its unquestioned superiority and efficiency is indicated by its widespread acceptance by leading Aural Specialists, by whom it is exclusively prescribed both in private and hospital practice.

Mr. Dent will gladly send full information of the various types and medical reports to Doctors, and is at all times pleased to arrange for a personal demonstration either at his address or theirs by appointment.

"MEDICAL PRESS OPINIONS" is a little Booklet of Reprints concerning **"ARDENTE-ACOUSTIQUE"** in all important Medical Journals.
May we send you a copy?

MR R. H. DENT'S
ARDENTE ACOUSTIQUE
TRADE MARK

An exclusive speciality is **"ARDENTE-ACOUSTIQUE" STETHOSCOPE,** which enables deaf members of the Faculty to continue their good work. Of this, a well-known heart Specialist, writing from Malta, says: "The **'ARDENTE-ACOUSTIQUE'** (Stethoscope) has been a godsend to me."

95, WIGMORE STREET, LONDON, W. 1
(Back of Selfridge's). PHONES: MAYFAIR 1380. MAYFAIR 4762.

Intestinal Disinfection

No. 2.

ALIMENTARY TOXÆMIAS

In our last advertisement, the subject of Alimentary Toxæmia was briefly discussed and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and being unabsorbed are non-toxic. They can therefore be administered freely without harm and are found to prevent the multiplication of the toxæmic intestinal bacteria and to considerably reduce them.

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim Capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99% (*vide Medical Press and Circular*, January 14th, 1914).

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three Capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

KEROL CAPSULES

TESTOGAN THELYGAN

For Men **For Women**

Formula of late Dr. Iwan Bloch.

After twelve years' clinical experience these products stand as proven specifics.

INDICATED IN

IMPOTENCE AND INSUFFICIENCY OF THE HORMONES.

They contain the hormones of the reproductive glands and of the glands of internal secretion.

Special Indications for Testogan:

Sexual Infantilism and Eunuchoidism in the male. Impotence and sexual weakness. Climacterium virile. Neurasthenia, hypochondria.

Special Indications for Thelygan:

Infantile sterility. Underdeveloped mammæ, &c. Frigidity. Sexual disturbances in obesity and other metabolic disorders. Climacteric symptoms, amenorrhœa, neurasthenia, hypochondria, dysmenorrhœa.

DIRECTIONS: A tablet three times daily after meals. Also in ampoules for intragluteal injection.

YOHIMBIN TABLETS AND AMPOULES (HENNING'S).

Dioxogen

(Trade H2 O2 12v Mark)

The standard of quality for Hydrogen Peroxide.

UNEQUALLED FOR STABILITY.

A potent yet harmless antiseptic and disinfectant for internal and external use.

"Dioxogen" may be used with assurance as to its activity and freedom from preservatives and impurities.

"Dioxogen" has the following points of merit which distinguish it from other makes of Hydrogen Peroxide:

Purity and very low acid content.
Strength 25% higher than B.P. standard.
Remarkable stability and keeping properties.

Dioxogen

SQUIRE'S AROMATIC APERIENTS.

KASENA

CASCARA and **SENNA** are still two of the most reliable and efficient aperients in use, but to obtain the most satisfactory results the preparations employed must be good, both as regards the selection of raw material used and the method of manufacture. Messrs. SQUIRE & SONS LTD. have had many years' experience in the treatment of these drugs and in the manufacture of products which present their properties in the most reliable and palatable form.

KASENA exhibits a proper combination of these two excellent laxatives, and affords the physician a trustworthy means of prescribing them where their use is indicated. It is a palatable syrupy elixir which retains the full activity of its constituents.

KASENA is specially suitable for delicate patients, women and children. It is supplied in bottles containing 6 and 12 fluid ounces, the usual dose being from 1 to 2 teaspoonfuls.

KASAK

KASAK is an elixir of Cascara giving the full therapeutic effects of the finest matured bark, while being free from its objectionable bitterness.

KASAK exhibits a marked TONIC effect, and its use is not followed by the constipating reaction so common to aperients of this nature. It is supplied in bottles containing about [illegible] and 16 fluid ounces. Dose for Children, 1 to 2 teaspoonfuls ; for Adults, 1 tablespoonful.

ADVANCE IN TREATMENT
of
Hyperchlorhydria and Associated Conditions

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory. They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra-indicated, especially in stubborn cases.

"Alocol" does not neutralize acid; it absorbs the excess colloido-chemically and at the same time leaves a sufficiency for normal gastric digestion. The outstanding advantage of "Alocol" as an antacid is that it removes from the system the causative acid radicle (Cl), instead of merely temporarily neutralizing it. "Alocol" can be used for prolonged periods without the slightest harmful effect.

A supply for clinical trial with full descriptive literature sent free on request.

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity. It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy, gastric and duodenal ulcer, gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis, flatulence, acid eructation and other symptoms common to gastric disease.

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

MIST. DAMIANÆ CO. (HEWLETT'S)

MIST. DAMIANÆ CO. (**Hewlett's**) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power MIST. DAMIANÆ Co. (Hewlett's) is powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.
Price in England, 12/6 per lb.

Introduced and Prepared only by—
C. J. HEWLETT & SON, LTD., 35 to 42, Charlotte Street, LONDON, E.C.2.

SOLE AGENTS FOR THE
HUMAN TUBERCLE BACILLUS SOLUTION (H.T.S.—DR. CROFTON).
The most powerful tubercle bacillus antigen yet produced.

ELIMINATION

THE evils of congestion, sluggish liver and biliousness can be speedily overcome by a course of "KUTNOW'S" Powder, which, by cleansing the blood stream of all impurities, revitalises the alimentary and digestive tracts to their normal state of vigour.

Further, its tonic properties gently eliminate all excess of Uric Acid without any of the stringent and harmful purgative effects of crude mineral salts.

Invaluable in all cases of Rheumatism, Gout and Lumbago, "KUTNOW'S" Powder has met with the unanimous approval of the Medical Profession.

May we forward you a sample bottle for either personal or clinical use?

O & S

OF IMPORTANCE
TO
MEDICAL MEN

SINCE the introduction of LYSOL nearly thirty years ago it was always guaranteed by the Original Makers to contain 50% of free cresols. Upon this percentage of free cresol was based its bactericidal powers.

DIRECTIONS for the use of LYSOL in the disinfection of fæces, the cleansing and disinfection of the skin before operations, the sterilising of instruments, etc., etc., which have been followed for a great number of years, were compiled only after exhaustive bacteriological tests.

FROM these tests it is certain that LYSOL in the given dilutions will perform the work expected from it, and in so far as the Original LYSOL is concerned certainly will do so.

ATTENTION, however, is drawn to the fact that there is now being sold as "LYSOL" preparations which contain less than 3% cresol, and it follows that should such preparations be used in the strength of dilutions indicated in the Original LYSOL that they will be practically useless for the purposes intended.

MEDICAL MEN are therefore asked to use and prescribe MARSHALL'S LYSOL, which is guaranteed to contain full 50% of free cresols, and is made according to the formula (now in our possession) followed by the Original Makers since LYSOL was first offered to the Medical Profession up to the present day.

Samples free to Medical Men.

LYSOL LTD. LONDON S.W.20.

Some Medical Opinions.

"The results of using this drug are so remarkable as to be almost incredible, and in nearly every case of uric acid disease I now prescribe it in lieu of Sod. Sal., etc. In several cases of intractable myalgia and rheumatism, these have yielded to Atophan after only indifferent results have been obtained with the usual salicylate treatment."

"I have used Atophan both in rheumatic and neuritic cases. I have cured a case of sciatica of a month's standing with 4 doses of Atophan and a relapse of chronic rheumatic arthritis of the knee joints cleared up in 48 hours under the same treatment."

"I find it a first-class cholagogue and, in my short experience, the best cholagogue I have prescribed."

"I have been using Atophan for some time, notably on a case of pain in the back due to rheumatism of muscular origin, in which I have tried every treatment I could think of. Atophan cut short the attacks very quickly, and also seems to have had a curative effect, for, after 6 doses or so, the attacks lessened in severity and finally ceased."

"I have used Atophan tablets in a case of persistent skin irritation, due, in my opinion, to uric acid in the blood, the patient being myself. Though not quite cured, I have received so much benefit that I should like to continue the treatment."

"I have already tried the Atophan on a case of fibrositis of the muscles of the neck and both scapular regions, and have attained excellent results."

A fine product from the celebrated laboratories of
E. SCHERING - *a guarantee of purity and reliability.*

ATOPHAN

TRADE MARK

Some Facts.

1. In the short space of from one to two hours there is an increase of from 100 to 300% of the uric acid excreted in the urine and a diminution in the uric acid content of the blood.

2. Many thousands of published clinical reports show that a rapid amelioration follows the administration of Atophan in **gout, rheumatism, and allied disorders.**

3. Atophan possesses powerful antiphlogistic properties. The chemosis following the instillation of mustard oil into the eye of a rabbit is prevented if Atophan be previously administered. It has been used successfully in pneumonia.

4. Atophan also has an analgetic action, as evidenced by the rapid relief from pain.

5. Atophan is a powerful cholagogue.

6. The immediate use of Atophan for acute articular rheumatism prevents cardiac complications and other ill-effects associated with salicylic therapy.

The summation of these properties in one preparation marks Atophan as the remedy, par excellence, in the treatment of rheumatism, gout, and allied disorders.

"PITUITRIN."

LANDMARKS IN ITS HISTORY.

1895.—OLIVER AND SCHÄFER discover that extract of the pituitary gland increases blood pressure (*Journal of Physiology*, xviii, 277).

1898.—HOWELL announces that the pressor principle can only be obtained from the posterior lobe of the gland (*Journal of Experimental Medicine*, iii, 245).

1905.—PARKE, DAVIS & Co. prepare posterior lobe extract, and issue same to co-workers in the Department of Experimental Medicine in U.S.A. and London.

1906.—A LONDON WORKER reports privately (April 3rd) " that the action of P., D. & Co.'s posterior lobe extract is similar to that of Adrenalin, but more prolonged in effect," this result being confirmed later by same worker (June 29th).

PARKE, DAVIS & Co. issue laboratory data regarding posterior lobe extract, dealing with toxicity, blanching experiments, effect on blood pressure, pulse, and flow of urine, illustrated with numerous kymographic tracings.

DALE discovers that contraction of uterus takes place when extract of dried ox-pituitary is given intravenously (*Journal of Physiology*, May 31st).

1907.—ALDRICH, of Parke, Davis & Co.'s Research Laboratory, publishes process by which the solution of the posterior lobe principle (later known as " Pituitrin ") is obtained (*Journal American Physiological Society*, December).

1908.—HOUGHTON & MERRILL report to the annual meeting of the American Medical Association (June), and

LOCKHART-MUMMERY & SYMES to annual meeting of the British Medical Association (July) on the properties of " Pituitrin."

BLAIR BELL describes action of infundibular extract on uterus (*Liverpool Medical and Chirurgical Journal*, July).

PROFESSOR PAL, Vienna, lectures on the effect of " Pituitrin " on arterial pressure (December); lecture reported with numerous tracings (*Wien. med. Woch.*, January 16th, 1909).

1909.—BLAIR BELL AND HICK on Pituitary Extract (*B.M.J.*, February 27th).

VON FRANKL-HOCHWART & FROEHLICH report contraction of uterus by " Pituitrin " (*Wien. klin. Woch.*, July 8th).

BLAIR BELL on clinical application of infundibular extract in obstetrical cases (*B.M.J.*, November 13th).

1922.—BURN & DALE (report to the Medical Research Council on biological standards) recommend that the strength of pituitary extract should be approximately 10 per cent., which has always been the strength of " Pituitrin."

1908—1925.—During these seventeen years some hundreds of clinical reports have been published on the use of " Pituitrin " in the numerous conditions in which it is indicated.

An Advance in Phosphorus Administration

OVALTINE

TONIC FOOD BEVERAGE

THE administration of phosphorus in a form that ensures a plentiful assimilation of this vital element is essential in preventing or restoring a lowered vitality—an all-important predisposing factor in many of the dangerous conditions which the practitioner is called upon to treat.

"Ovaltine", a concentration of malt, milk and eggs—in judicious proportions—is unusually rich in organic phosphorus compounds. The process of manufacture is conducted at such low temperatures that no molecular decomposition of these labile compounds takes place, whilst the vitamine content is preserved unimpaired.

Patients do not readily tire of the delicious flavour of "Ovaltine"; it rapidly improves nutrition without disturbing digestion or causing constipation.

A most successful preparation in the dietary treatment of tuberculosis, neurasthenia, hysteria, general debility, fevers, influenza, difficult feeding cases due to stomach or duodenal ulcer, etc.

A liberal supply will be sent free to medical men on request.

INFANT DIET MEAD'S MATERIALS

SUMMER DIARRHŒA

In Infants.

INFANT Specialists usually agree that *no* carbohydrate should be added to the diet of an infant with Fermentative Diarrhœa (green stools).

Such infants require a special *temporary* diet that is higher in protein and low in carbohydrate or sugar. Then, when the stools become normal, the usual modification of cows' milk, water, and Dextri-Maltose may be gradually resumed.

Protein Milk, the ideal corrective diet for summer diarrhœa, may be very simply and easily prepared with Mead's Casec as follows :—

16 ozs. of Cows' Milk,
16 ozs. of Water,
2/3 oz. (2 envelopes) Mead's Casec.

Samples of CASEC, together with full information regarding its use, will be sent to Physicians on request.

THE MEAD POLICY.

There are no feeding directions on the tins of Mead's Infant Diet Materials, thus leaving the feeding strictly under professional supervision. Literature supplied only to doctors, hospitals and clinics.

FOR THE INFORMATION OF MEDICAL PRACTITIONERS.

IMPORTANT NOTICE.

With the object of affording Medical Practitioners of the district facilities for obtaining Scientific Investigations in reference to their patients, Boots the Chemists have made arrangements by which the Pathological, Bacteriological, Serological, and Chemical Laboratories of the Royal Institute of Public Health are available for such purposes.

Further information and the necessary outfits required can be obtained from the Manager of any Branch of Boots the Chemists.

Sinubérase

Contains VITAMINS and LACTIC FERMENTS that ensure the healthy condition of the entire Digestive System.

Constituents :		*Principal Indications :*
Lactic Ferments	Bulgarian B. Paralactic B. Bifid B.	Enteritis. Auto-toxæmia. Intractable Diarrhœa.
Protoplasm of Brewer's Yeast.		Infantile Diarrhœa. Dysentery. Skin Diseases.
Extract of Barley Malt.		Infectious Diseases.

Sinubérase contains selected lactic ferments in full activity—viz., *Bulgarian bacilli*, which liberate lactic acid, chiefly in the large bowel; *diplo-bacilli*, which develop in the small bowel, while the *paralactic bacilli* are useful on account of liberating lactic acid in *inert stomachs*, and are specially useful in cases of dyspepsia. The association of these three kinds of bacilli in Sinubérase yields the maximum effects, which are further increased by the addition of the active principles of yeast and of barley malt.

The usual effects following upon the administration of Sinubérase are :—

> Improved appetite, clean tongue, suppression of gastric disorders and intestinal infection, and the neutralisation of microbian virulence. Infective symptoms disappear, vital degenerescence is arrested, the skin assumes a healthy colour. A **real "rejuvenation" of the system is achieved.**

THALES, THE FOUNDER OF GREEK GEOMETRY, ASTRONOMY AND PHILOSOPHY.—The Ionians were the pioneers of Greek intellectual progress. Thales, Solon, Æsop, Pythagoras and Æschylus were Ionians of the 7th and 6th centuries B.C. Thales of Miletus was the chief of the "Seven Wise Men" of Ionia. He is said to have predicted the eclipse of May 28th, 585 B.C., to have discovered that the circle is bisected by its diameter, and that the angles at the base of an isosceles triangle are equal. He used his knowledge to aid seafarers, calculating the distance of ships at sea and teaching how to steer by the Little Bear (as being nearer the Pole) instead of by the Great Bear. He determined the heights of pyramids by the length of their shadows, divided the year into 365 days, and discovered that the circuit of the sun between the solstices is not always uniform. Thales and the other wise men of Ionia co-ordinated the knowledge they inherited from the past with that which they acquired for themselves. From this combined knowledge they developed ideas and abstract principles which enabled them to gain further wisdom; this scientific habit the world first learned from them. Thales also worked out a theory of the material cause of the Universe, thus earning for himself the title of *philosopher*, "a lover of knowledge for its own sake."

DATE: 640-546 B.C.

COPYRIGHT

The "BRITISH MEDICAL JOURNAL" says:
"Benger's Food has by its excellence established a reputation of its own."

Benger's Food is standardised by the Medical Profession for all illnesses involving or arising from weakness of the digestive system in Infants, Invalids and the Aged.

By means of Benger's Food, fresh cows' milk can safely be given even to the weakest stomachs. Benger's Food contains the active enzymes of natural digestion (*Amylopsin* and *Trypsin*), which act upon the casein of milk and the farinaceous material of the Food in such a manner as to render them easy assimilable.

The precise degree of digestibility of Benger's Food can be regulated by allowing the mixture to stand for a varying period at one stage of its preparation. A useful average period is 15 minutes, but in extreme cases, and with very young infants, this can be increased to 30 minutes or more.

NOTE.—COMPLETE PRE-DIGESTION OF BENGER'S FOOD AND MILK IS NOT POSSIBLE. As health and natural digestion improve, the extent of the PARTIAL self-digestion of the Benger's Food and milk may be gradually reduced. The digestive organs can in this way be given a suitably-regulated exercise for steady progress to ordinary diet.

Benger's Food is itself of high food value, and with milk provides a complete food in the form of a delicate cream, rich in nutrition.

Medical Men may obtain full particulars of any of Benger's preparations post free on request.

'Byno' Hypophosphites

Trade Mark

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally.

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt, which is the basis of the preparation.

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations; in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis; in asthenia of the aged, and in a diversity of conditions where a general tonic and digestive is indicated.

COMPOSITION:

Calcium Hypophosphite	2 gr.	Iron	¼ gr.	Nux Vomica Alkaloids (equal to Strychnine)	$\frac{1}{40}$ gr.
Potassium	2 „	Manganese ...	¼ „	'Bynin' Liquid Malt ...	1 oz.
Sodium	2 „	Cinchona Alkaloids	1½ „

HAY FEVER

A locally-applied antiseptic is now acknowledged as the best treatment for hay fever.

Because of its peroxide and aromatic constituents, you cannot do better than prescribe Sanitas for spraying or swabbing the nostrils of patients suffering from this irritating complaint.

Sample gratis to any medical practitioner.

Cow and Gate Milk Food

Professional Support

explains the growing sales of COW & GATE MILK FOOD.

When purity and ease of digestion are conceded to all, there still remain sound reasons why Doctors prefer Cow & Gate Milk Food. It is not a frustration of Nature's laws; it is made from the milk of the Home Country's finest cows. Its vitamine values, and its progress in tiny human organs are the same as in the case of healthy breast milk. By bringing expert evidence, rather than by broadcasting tables of figures, has COW & GATE MILK FOOD won and retained its place.

No matter how difficult the case, COW & GATE MILK FOOD meets it entirely.

The Full Cream strength is most suitable for pre-natal feeding and for infants *over* 3 months. Half Cream for direct feeding of infants *up to* 3 months. Ask your doctor *his* opinion!

OF ALL CHEMISTS,

Dept. 1, COW & GATE HOUSE, Guildford, Surrey.

A new adjuvant in the

Diagnosis of Gonorrhoea in the Female

prepared from the formula of Prof. Opitz and Dr. L. Danin.

Gonotest-Julia

(Protected in Germany and Abroad).

The thorough reliability of this diagnostic method renders microscopical examination unnecessary. By testing the reaction of the vaginal secretions, the presence of the gonococci and their subsequent disappearance can be estimated in a few seconds. This test which is performed without injection is more certain than any method at present in use. (See the *Münchener Medizinische Wochenschrift*, No. 18, 1925.)

Rebuilding Normal Weight

In convalescence, wasting diseases, and malnutrition generally, patients frequently find it impossible to take or retain a sufficiency of fatty foods.

In such cases "Skippers" are found to be a valuable addition to the usual diet.

"Skippers" are Norwegian Brisling packed in and impregnated with olive oil—the purest and most expensive of the seventeen recognised commercial grades.

Consequently they convey all the well-known nutritive and medicinal virtues of olive oil together with the natural phosphates of the fish, but without the unpleasant after-effects commonly associated with fish packed in oil.

In flavour "Skippers" are delicate and distinctive, and fastidious invalids often enjoy them whilst refusing other fatty foods.

Owing to the special methods used in their cooking and preparation, "Skippers" are extremely easy of digestion, notwithstanding their high fat content.

"Skippers"

FREE FROM HARD SCALES OR BONES

'Skippers' in Oil or Tomato are guaranteed to contain no preservatives.

The name Angus Watson on any ready-to-serve food means the best of its kind.

ANGUS WATSON & CO., LIMITED, NEWCASTLE-UPON-TYNE.

HUMANISED
(PRESCRIPTION)
GLAXO

is a new form of dried milk with a low protein content and yet the same amount of fat as average breast milk. When reconstituted with hot, boiled water (1 in 8), it has a composition almost identical with that of average breast milk, with low protein content and high lactose percentage, as can be seen from the analyses below :—

Prescription Glaxo . .	6.9	Lactose
Human Milk	7.0	
Prescription Glaxo . .	3.1	Milk-fat
Human Milk	3.3	
Prescription Glaxo . .	1.7	Protein
Human Milk	1.7	

GLAX-OVO

"EVERY DROP NOURISHES"

is a new food-drink that contains a definite quantity of the "Vitamin Concentrate" (Ostelin, see below) blended with milk, malt extract and cocoa. Prepared in a minute with boiling water, Glax-ovo is especially useful for expectant and nursing mothers, as well as for cases of Neurasthenia, Sleeplessness, Influenza, Coughs, Colds, etc.

Note.—This "Vitamin Concentrate," which is incorporated in Glax-ovo alone, is now sold under the registered name of "OSTELIN." In this form the actual substance is diluted with glycerine so that three drops of the glycerine suspension are equivalent to one teaspoonful of cod-liver oil.

Prepared by the Glaxo Laboratories. Samples and special literature concerning these products will be sent gladly, on receipt of name and address to Glaxo (Med. Dept.), 56, Osnaburgh Street, London, N.W. 1.

What is Nonspi?

NONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless, NONSPI need be applied, in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

Sterile food products

It is the fashion to-day to state that a certain product contains only a certain number of bacteria. Sometimes, products are said to be "sterile." No milk product, without irretrievable damage, can be rendered sterile in the bacteriological sense, nor did nature ever intend them to be so. It is the kinds of bacteria in a food product that are significant and not the numbers. Infants' foods which have been dried at high temperatures are completely robbed of lactic-acid organisms, but contain, unharmed, numbers of putrefactive organisms, particularly when cereal products form one of the constituents.

HUMANISED TRUFOOD

Humanised Trufood is so carefully treated as regards temperature that no vital characteristic of the milk is changed, but all disease organisms are destroyed, while the more virile types of lactic-acid organisms survive, and completely inhibit putrefaction on reconstitution. At the ninth month from birth, Trufood Full Cream supplies the increased nutrition which the infant's digestive organs are then prepared to assimilate. Containers are air-tight—proof against contamination—and are dated to ensure fresh consumption. Samples, adequate for thorough clinical trial, together with descriptive literature, will be sent, post free, on request.

May we post you reprint of lecture: "Some aspects of the composition of infant foods"?

IRVING'S
YEAST-VITE TABLETS.
The New Yeast Vitamin Treatment.

We hold high medical testimony showing efficacy in cases of **DIABETES, SEPTICÆMIA, PYÆMIA,** skin blemishes and other disorders of the blood.

They act with quick stimulating effect on the pancreas, liver and kidneys.

The antipyretic, anodyne and analgesic action is more pronounced than that of the usual coal tar derivatives, without unfavourable reaction, and have the advantage of rapid assimilation.

Of value as a vitaliser and rejuvenator.

Recommended as a nerve sedative, and of considerable value in moderating menstrual and labour pains.

We supply (without charge) to physicians, hospitals, clinics and nurses sufficient supplies for exhaustive tests.

IRVING'S YEAST-VITE LABORATORIES,

Owing to its remarkable sedative and antispasmodic properties

TRADE MARK **'LUMINAL'** BRAND
PHENO-BARBITAL

is considered by many authorities as the most effective remedy for controlling the seizures in epilepsy.

'Luminal' is also highly recommended as a sedative in various other affections, especially in gastric and cardiac neuroses, chorea, neurasthenia, pertussis, exophthalmic goitre, migraine, encephalitis, drug habituation, and in pre- and post-operative cases.

As a hypnotic 'Luminal' is especially indicated in cases of marked insomnia and excitement in mental diseases occurring in Sanatorium and Asylum practice.

Catarrhs and Diseases of the Respiratory Tract

NEW TREATMENT AT

HARROGATE

(Member of the British Spa Federation)

THE new treatments at Harrogate include a most up-to-date Nose and Throat Spray Treatment for the cure and relief of Catarrhs and Diseases of the Respiratory Tract. Harrogate is the only Spa in the world using the Natural Sulphur Water in atomised condition for this treatment.

¶ Another new installation is the Artificial Mountain Sun Treatment (Ultra Violet Rays), in which such great interest is now being taken by the Medical Profession.

¶ The above treatments, like the other 100 Harrogate treatments (with 87 different mineral waters) are given by Medically Trained, Medically Examined and Medically Certificated Male and Female Nurses

Complimentary and reduced price facilities are offered to enable Members of the Medical Profession personally to test the claims of Harrogate.

West Ham Union.

DISTRICT MEDICAL OFFICER (MALE).

The Guardians invite applications for the appointment of Medical Officer (Male) for the Nos. 1, 2, 17, 21, and 23 Districts, situate in the Northern Area of the West Ham Parish of the Union, at the salary of £650 per annum, rising by £25 annually to a maximum of £700 per annum, with a bonus at present of £214 per annum and £50 annually towards the upkeep of a motor-car for use in connection with the duties of the office, all drugs, medicines, and appliances, with surgery, being provided by the Guardians. The salary will be inclusive of any fees payable to the officer under any Acts of Parliament or Orders of the Ministry of Health, and any such fees paid to the Officer are to be repaid by him, within seven days, to the Treasurer of the Guardians.

Candidates must be fully qualified Medical Practitioners, and the gentleman appointed will be required to devote the whole of his time to the duties of the office, and to reside as near as possible in the centre of the District.

Forms, upon which applications must be made, can be obtained at my office or will be forwarded upon receipt of a stamped and addressed foolscap envelope, and must be returned not later than 10 A.M. on Monday, the 6th July, 1925.

It is a condition of appointment that the successful candidate, before taking up his duties, shall become a member of a trade union or vocational society.

Canvassing the Guardians, either directly or indirectly, is prohibited and will disqualify.

By order of the Board,
THOMAS SMITH, Clerk.

Board Room, Union-road, Leytonstone, E. 11,
19th June, 1925.

London Lock Hospital, 283, Harrow-

road, London, W. 9.

The Board of Management invite applications for the appointment of SECOND HOUSE SURGEON (Male or Female) at the Female Lock Hospital, Harrow-road, W. 9. Salary at the rate of £150 per annum, with furnished rooms, full board, and washing.

Candidates, who must be doubly qualified and duly registered, should send in their applications by 10 A.M. on July 6th, accompanied by copies of three recent testimonials, to the Secretary, from whom further particulars can be obtained if desired. The appointment is for six months, commencing August 1st, 1925.

By order of the Board,
June 19th, 1925. HY. J. EASON, Secretary.

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICER (MALE).

The Guardians invite applications for the above position at the MILL ROAD INFIRMARY, Liverpool, at a salary at the rate of £200 per annum, together with the usual resident allowances.

Candidates must be single, fully qualified, and registered.

Appointments will be for the period of one year in the first instance, subject to extension for a further period not exceeding twelve months, at the option of the Guardians.

Applications to be sent, stating age, qualifications, &c., with copies of three recent testimonials, to the undersigned, NOT LATER than SATURDAY, 4th JULY, 1925.

G. W. COSTER, Clerk to the Guardians.
Union Offices, Brougham-terrace, Liverpool.

The University of Sheffield.

Applications, with copies of testimonials, should be sent to the undersigned not later than July 15th, 1925.

J. ALBERT DAVIES, Secretary.

Sculcoates Union, East Yorkshire.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians invite applications from qualified persons of either sex for the full-time appointment of Resident Assistant Medical Officer at the INSTITUTION INFIRMARY, Beverley-road, Hull.

Applications will be considered from persons between and including the ages of thirty and forty years only.

The number of sick inmates is about three hundred.

The salary will be at the rate of £350 for the first year, £375 for the second year, and £400 for the third and each succeeding year (no bonus); and board and other usual allowances (valued at £150 for superannuation purposes) will be provided.

The salary and emoluments will be subject to deductions under the provisions of the Poor-law Officers' Superannuation Act, 1896.

There will be no fees in addition to the salary.

The Infirmary is not under separate administration. The staff comprises a Medical Officer, a Superintendent Nurse, and sixty-five other Nurses.

Particulars of the duties will be sent on request.

Applications, setting out qualifications, dates of registration, experience, &c., together with copies of three recent testimonials, must be sent so as to be received by me not later than Monday, 6th July next.

Selected candidates will receive notice when and where to attend.

W. BARROW, Clerk to the Guardians.

12, Harley-street, Hull, 18th June, 1925.

County Borough of Bury.

The Corporation of Bury are prepared to receive applications for the post of ASSISTANT MEDICAL OFFICER OF HEALTH, ASSISTANT SCHOOL MEDICAL OFFICER, and ASSISTANT TUBERCULOSIS OFFICER at a salary of £600 per annum.

The principal duties will consist of the Medical Inspection of School Children, and the Diagnosis, Treatment, &c., of Tuberculosis, but the gentleman appointed will also be required to assist the Medical Officer of Health in his other duties as the Health Committee may direct.

Applicants must be registered Medical Practitioners, must possess the Diploma of Public Health, and must have had at least three years' experience of Post-graduate Medical work. They must have had special practical experience in the Diagnosis and Treatment of Tuberculosis.

The gentleman appointed will be required to reside in the Borough in a house belonging to the Corporation, for which a rent of £40 per annum will be charged.

Application forms and terms of appointment can be obtained from the Medical Officer of Health, Clough-street, Bury. Applications, endorsed "Assistant Medical Officer of Health" and accompanied by copies of three recent testimonials, must be delivered not later than the first post on Saturday, the 11th July, to the undersigned.

RICHARD MOORE, Town Clerk.

Municipal Offices, Bury, 19th June, 1925.

Borough of Dover.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Dover invite applications for the above appointment from Medical Practitioners between thirty and forty years of age who hold a Diploma in Sanitary Science. Salary £750.

The applicant appointed will be required to commence his duties as soon as possible and to devote his attention principally to work under the Aliens Order, 1920. Colloquial French and German will be a recommendation.

Further details of the duties and terms and conditions of the appointment may be obtained of the undersigned, to whom applications, accompanied by copies of testimonials, must be delivered by the 8th July.

R. E. KNOCKER, Town Clerk.

Town Clerk's Office, Brook House, Dover, 17th June, 1925.

Manchester Royal Infirmary and

DISPENSARY.—Appointment of an HONORARY ASSISTANT GYNÆCOLOGICAL SURGEON.—The Board of Management invite applications for the above appointment.

Candidates must be Graduates in Medicine of a British or Irish University, or a Fellow of one of the Royal Colleges of Surgeons of the United Kingdom.

Candidates are required to forward Diplomas, original testimonials, and a certificate of age with their applications, addressed to the Secretary, on or before 9 A.M. on Saturday, July 18th, 1925, from whom also a copy of the Rules can be obtained.

Candidates are required to furnish forty-five copies of their applications and dated testimonials, addressed to the Secretary, for distribution prior to the meeting of the Committee.

Canvassing, directly or indirectly, is forbidden, and the Committee reserve to themselves the right, on proceeding to election, to take into consideration any complaint that canvassing on behalf of any candidate has taken place.

By order.

FRANK G. HAZELL, Gen. Supt. and Secretary.

Manchester Royal Infirmary, 19th June, 1925.

City of Birmingham.

ASSISTANT MEDICAL OFFICER.

The Asylums Committee invite applications from duly qualified and registered Medical Men and Women, under thirty-five years of age, for the post of Assistant Medical Officer at one of the City Mental Hospitals under their control, at a commencing salary of £350, rising to £400 at the end of a year's satisfactory service, with apartments, board, and laundry.

Candidates possessing, or willing to obtain, the D.P.M., and who have done a House appointment in a General Hospital, will be given preference.

The candidate appointed will be required to join the Asylums Officers' Superannuation Scheme.

Applications, accompanied by copies of three recent testimonials and endorsed "Assistant Medical Officer," should be delivered to the undersigned not later than July 4th, 1925.

The appointed candidate will not be required to take up duties until the end of September.

Canvassing, either directly or indirectly, will be deemed a disqualification.

F. H. C. WILTSHIRE,
Clerk to the Committee of Visitors.

Council House, Birmingham.

Surrey County Council.

ASSISTANT MEDICAL OFFICERS IN THE PUBLIC HEALTH DEPARTMENT.

Applications are invited for the appointment of Male Assistant Medical Officers. Candidates must possess a qualification in Public Health, and have had experience in one or other of the following special branches: (i.) Tuberculosis, (ii.) Venereal Diseases, (iii.) Mental Defect, (iv.) Ante-natal Hygiene. The officers appointed will be required to undertake such other public health duties as may be allocated to them. They will be on the Staff of the County Medical Officer of Health, must reside in the County, and devote the whole of their time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum.

The appointments will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' written notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove-crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointments should be addressed.

Last day for receipt of applications: Tuesday, 30th June, 1925.

Canvassing directly or indirectly will disqualify.

T. W. WEEDING, Clerk of the County Council.

County Hall, Kingston-upon-Thames, 8th June, 1925.

The Crossley (Maternity) Hospital,

Ancoats, Manchester.—Applications are invited from Medical Women for the post of half-time RESIDENT MEDICAL OFFICER. Vacancy now. Salary £50 per annum, with board, residence, and laundry. Appointment for six months. Applications, with testimonials, to be sent to Commissioner Adelaide Cox, 280, Mare-street, London, E.

The Jessop Hospital for Women,

Sheffield.

GYNÆCOLOGICAL AND MATERNITY DEPARTMENTS.

(93 Beds.)

The Board of Management invite applications for the post of SENIOR RESIDENT OFFICER (Male), which has unexpectedly become vacant, for the remaining period of the year 1925.

Salary at the rate of £250 per annum, with board, residence, and laundry.

The duties include charge of the Maternity Dept. and the Senior Surgeon's Gynæcological Beds, and are to commence as soon as possible after July 1st.

Applications, stating age and experience, with copies of recent testimonials, should be forwarded immediately to the undersigned.

H. B. SHELSWELL, Secretary.

SECOND ASSISTANT MEDICAL OFFICER.

Wanted for the TOWNLEYS HOSPITAL, Farnworth, near Bolton, a Second Assistant Medical Officer for a period of one year.

The Hospital has accommodation for 500 patients, is a recognised training school for nurses, and is equipped with all modern requirements.

There is a Resident Medical Superintendent and a Resident Assistant Medical Superintendent.

Salary £225 per annum and rations, furnished apartments, washing, and attendance (subject to the usual deduction under the Poor-law Officers' Superannuation Act, 1896).

Forms of application, together with conditions of appointment (for which a stamped addressed foolscap envelope must be enclosed), may be obtained from me. Last day for applications 13th July, 1925.

H. I. COOPER, Clerk to the Guardians.

28, Mawdsley-street, Bolton, 18th June, 1925.

Notts. Education Committee.

SCHOOL DENTIST.

The Notts. Education Committee invite applications for the appointment of a School Dentist (Man or Woman).

The present salary will be at the rate of £500 per annum.

The officer appointed must be a duly qualified and registered dentist, and will be required to devote his whole time to the inspection and treatment of school children.

He will be attached to the staff of the Chief School Medical Officer, and will be required to work under his direction and control. Reasonable travelling expenses will be paid, and the successful candidate must reside in whatever part of the county may be approved by the Education Committee. The appointment may be determined by three months' notice on either side.

Applications, stating age, qualifications, and previous experience, must be accompanied by copies of not more than three recent testimonials, and should be addressed to the undersigned not later than 11th July, 1925.

T. E. HOLMES, County Medical Officer.

The Shire Hall, Nottingham, 22nd June, 1925.

Ilford Urban District Council.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Urban District Council of Ilford invites applications from legally qualified Medical persons of both sexes for the office of Assistant Medical Officer of Health for duties in connection with Maternity and Child Welfare Work, School Medical Inspection, and General Public Health Work. Candidates for the appointment must have had special experience in Midwifery since qualification, and subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had definite experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus).

The person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Council's Maternity Home, and to enter into a contract with the Council for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a satisfactory medical examination.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office at the Town Hall, Ilford, not later than Wednesday, the 1st day of July, 1925.

Canvassing members of the Council, directly or indirectly, is prohibited and will disqualify.

By order.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone:* GERRARD 3543 (3 Lines).

Established by Bovril, Limited, to provide an efficient and reliable transfer service for the Profession at minimum Charges.

Under the personal direction of **Dr. J. FIELD HALL** and **Mr. J. C. NEEDES,** who have both had many years' experience as Medical Transfer Agents.

An Accountant's Certified Report is required in respect of every Practice or Partnership the disposal of which is undertaken by the Agency.

The commission chargeable in respect of any Practice in Great Britain placed exclusively in the hands of the Agency for transfer has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50). In the case of Foreign and Colonial Practices similarly placed the maximum is seventy-five pounds (£75).

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS. Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. DEATH VACANCY.—CORNWALL.—Pleasant Hospital Town.—Old-established General PRACTICE, held by the late Incumbent over 40 years. Average income for last 3 years £1173, including appointments and panel of nearly 500. Fees 3s. 6d. to 21s. Very nice house and garden. Premium for house (freehold) and practice £3500.
2. BORDERS OF NORFOLK AND SUFFOLK.—Very old-established PRACTICE, situated in a pleasant Country Town. Population of area covered by practice about 15,000. Steady average income for last ten years of £1500. Good appointments and panel of 600–700. Fees 2s. 6d. to 21s. Exceptionally nice house, with 3 sitting-rooms, 7 bedrooms, and all modern conveniences. One acre of garden with good tennis-lawn, &c.; rent £60 p.a. Sport of all kinds. Premium £3000.
3. KENT.—COUNTRY PRACTICE.—PARTNERSHIP.—A One-third Share (to commence with) in a very old-established Mixed General Practice. Steady average income of £4500. A further share can be bought later. Total panel of 2300. Union and other appointments. Nearest opposition 5 miles. Advice and medicine 3s. 6d.; visits and medicine 4s. to 21s. Midwifery 2 to 15 guineas. Excellent house, with 2 acres of garden, tennis lawn, &c. Price, freehold, £2500, or rented at £150. Premium £3000.
4. NORTH OF ENGLAND.—Seaport Town (Population 125,000).—Well-established Mixed-class PRACTICE, worth last year over £3000, including appointment (£40) and panel of nearly 2000. Visits 3s. 6d. and 5s. About 100 cases of Midwifery yearly at 2 guineas. Good house, containing surgery, waiting and consulting rooms, 3 reception, 4 bedrooms, and dressing room. Rent, on lease, £120 p.a. Premium £2500, part by instalments. Exceptionally good introduction can be given. Golf, fishing, tennis, &c., and educational facilities.
5. BIRMINGHAM.—Old-established Industrial PRACTICE, averaging nearly £2500 p.a., including 3200 panel patients. Visits 2s. 6d. and 3s. 6d. Only about 30 cases of Midwifery yearly at 2½ guineas. Good house, containing excellent surgery and waiting-room (separate entrance), 2 reception-rooms, 5 bedrooms, &c.; large garden; garage; gas and electric light. Held on lease at £84 p.a. Premium £3600. Would suit two friends in partnership.
6. STAFFORDSHIRE.—Old-established General PRACTICE. Income for the last year over £1500, including a panel of between 1500 and 1600. Fees, advice and medicine 2s. 6d. to 5s.; visits 2s. 6d. to 7s. 6d., medicine extra. Large house with 8 bedrooms, central heating, about ½ an acre of garden; rent £120, or will be sold for £2400, freehold. Premium £2200.
7. LANCS.—Large Town.—DEATH VACANCY.—Old-established non-panel PRACTICE. Income for the immediate past year £1250. Good fees. Eleven-roomed house, freehold; would be sold for £2500, or let on lease. Premium £1000.
8. HOMŒOPATHIC PRACTICE, situated in a pleasant County Town in the Eastern Counties. Held 30 years by Vendor, who is retiring. Receipts average over £2000 p.a. for the past 3 years. Visits 3s. 6d. to 7s. in the town and 1 to 4 guineas outside. About 12 Midwifery cases yearly from 3 guineas upwards. Good house (3 reception and 7 bedrooms, &c.), with garden; Vendor's freehold. Price £1400. Premium for practice only £1800.
9. BRISTOL.—Outlying District.—Small Middle-class PRACTICE, offering large scope to an energetic man. Average income of £750. Panel of nearly 1200. Advice and medicine 2s. 6d.; visits and medicine 4s. 6d. to 6s. House with 2 sitting and 4 bedrooms, professional rooms, bathroom, small garden. Vendor's freehold, price £1000. Premium £1000.
10. SURREY.—PARTNERSHIP, with view to Succession in 2 or 3 years' time.—The Two-thirds Share of a very old-established Practice, held 46 years by present Incumbent, and situated in a charming Residential Town. Present receipts (which on account of Vendor's advancing age are capable of increase) over £1000 a year, including appointments £125 and panel of about 1000. Patients are mixed class. Fees 3s. 6d. to 10s. 6d. No Midwifery. Good house available; rent £70 a year, on lease.
11. KENT.—Small Town, within one hour of London.—Old-established Mixed General PRACTICE. Income last year £2000, including valuable appointments believed to be transferable, and panel of about 1250. Fees 3s. to 10s. About 20 cases of Midwifery yearly at 2 to 5 guineas. Excellent house, well situated, containing 2 reception and 8 bedrooms, separate entrance to professional rooms; standing in its own grounds of ¾ of an acre. Vendor's freehold, price £2300, part on mortgage. Good Hospital and vendor on staff. Premium £2700.
12. WEST OF ENGLAND.—Residential Town.—A Half Share, with succession in 2 or 3 years' time, is offered in a sound, mainly consulting, Practice, non-panel and non-dispensing, but offering large scope for general work if desired. Income over £1500. Fees from 10s. 6d. to 2 guineas. Large house, in the best part of town, with garden; rent £200 p.a. on lease. Premium £1500, payable £1000 cash, and £500 within 12 months.
13. PARTNERSHIP.—South of England.—In a delightful country district within 40 miles of London, the Half Share of an unopposed Practice, averaging over £1700 p.a. (last year £1778) can be acquired by a gentleman about 30 years of age and accustomed to good society. Visits 7s. 6d. to 21s. Under 20 cases of Midwifery yearly at from 3 to 20 guineas. House probably available on rental at about £80 p.a. Premium for share 2 years' purchase. Scope for increase.
14. NEWCASTLE-ON-TYNE AREA.—Old-established Middle- and Working-class PRACTICE, held by Vendor 20 years. Steady average income of nearly £1400. Panel of 1036. Advice and medicine 3s. 6d.; visits and medicine 4s. About 30 cases of Midwifery a year at from 2 guineas. Good corner freehold; price £1800. Premium £1500.
15. LONDON, S.W.—PARTNERSHIP.—A Half Share is offered in an old-established Mixed General Practice, situated in an outlying suburb. The average income for the last three years is over £2500, including a panel of about 1100. Visits from 3s. 6d. upwards. Not much Midwifery from 3 guineas. Good corner house, with 2 reception and 5 bedrooms, &c. Price £1600, or will be let. Premium 2 years' purchase.
16. NEW ZEALAND (North Island).—In an increasing and quite detached Suburb of a large town, amidst most beautiful scenery of harbour and sea, an old-established PRACTICE is for disposal. Cash receipts last year £1546, and first 3 months of this year £473, including Lodges worth about £380. Fees 7s. 6d. to 10s., medicine extra and up to £2 2s. outside suburb. Midwifery 4 to 5 guineas, outside suburb 5s. per mile. Good substantial 2-storied house, with 8 rooms, bathroom, kitchen, garage. Rent £150. Premium £1200.
17. INDIA.—ASSISTANTSHIP with view to PARTNERSHIP.—A well-qualified single man, between 30 and 35 years of age, is required on a 2 years' engagement in a practice producing £7000 a year. Salary £800—£850 a year, plus board and lodging. Prospect of a sixth share (with increase later) at 1 year's purchase—payable by instalments—at termination of engagement.

Profits accruing to Bovril, Ltd., from the Agency will be allocated amongst recognised Medical Charities.

Full Schedule of Terms and Conditions will be forwarded on application.

SOL. PARA-SPLEEN CO.

(HARROWER)

SERGENT AND BINET, of Paris, have found that in advanced tuberculous cases the calcium content varied between 100 and 110 mg., while in benign cases it varied between 120 and 130 mg. Extensive laboratory tests and clinical findings show that spleen substance, in combination with parathyroid, renders the blood calcium more stable. Therefore *Sol. Para-Spleen Co. (Harrower)* is of value in the treatment of

TUBERCULOSIS

in which calcium loss is the rule. A sufficient quantity to permit of an adequate test will be sent *free* on request.

Each package contains 15 ampoules of full-strength solution for hypodermic administration.
